## TEACHERS' UNDERSTANDING AND OPERATIONALISATION OF 'SCIENCE CAPITAL'

### ABSTRACT

Across the globe, governments, industry and educationalists are in agreement that more needs to be done to increase and broaden participation in post-16 science. Schools, and teachers, are seen as key in this effort. Previous research has found that engagement with science, inclination to study science, and understanding of the value of science strongly relates to a student's science capital.

This paper reports on findings from the pilot year of a one-year professional development (PD) programme designed to work with secondary school teachers to build students' science capital. The PD programme introduced teachers to the nature and importance of science capital and thereafter supported them to develop ways of implementing science capital-building pedagogy in their practice. The data comprises interviews with the participating teachers (n=10), observations of classroom practices, and analyses of the teachers' accounts of their practice. Our findings suggest that teachers found the concept of science capital to be compelling and to resonate with their own intuitive understandings and experiences. However, the ways in which the concept was operationalised in terms of the implementation of pedagogical practices varied. The difficulties inherent in the operationalisation are examined and recommendations for future work with teachers around the concept of science capital are developed.

**Keywords:** science capital, teacher professional development, teacher conceptualisations

## INTRODUCTION AND BACKGROUND

Increasing and broadening participation in science, technology, engineering and maths (STEM) is a key national policy concern both in the UK (e.g. CBI, 2012; House of Lords, 2012) and elsewhere (e.g. Marginson, Tytler, Freeman & Roberts, 2013; PCAST, 2010). Yet despite decades of interventions, participation in science still remains strongly patterned, with working-class, women and some minority ethnic groups remaining under-represented in post-16 science, particularly in the physical sciences and engineering and at higher levels (CBI 2012; Johnson, 2011; Lord Sainsbury, 2007; Royal Society, 2008; Tomei, Dillon, & Dawson, 2015). **This disparity in participation matters for several reasons. Many commentators have discussed the need for more science graduates and recruits to scientific careers in order to secure economic competitiveness (European Commission, 2004; UK Department for Education and Skills, 2004). It has also been argued that the production of new scientific knowledge should be informed by the insights and experiences of the broad and varied society it seeks to serve (Barton, 2003; Miller, 2010). In terms of social justice, meanwhile, research has shown that science qualifications can ‘open doors’ to a range of careers both in and out of science, and that science graduates are likely to earn more in their lifetimes than non-science graduates (de Vries, 2014). Perhaps not surprisingly, however, recent research which has examined the varied science participation rates among young people have found that some have more opportunities to participate, and receive more support, than others (Carlone, Scott and Lowder, 2014; Maltese, Melki and Weibke, 2014).** The study reported in this paper is part of a larger UK-based programme of research aimed at investigating and working with the concept of ‘science capital’ (see theoretical framework below) as a way of interpreting and theorising established patterns of participation and moreover providing a conceptual framework for informing initiatives aimed at addressing the disparity, and positively influencing science participation and engagement.

A student’s experience of school science and science teaching is a key factor in influencing his or her interest in and attitudes towards science (den Brok, Fisher & Scott, 2005; Osborne & Collins, 2001; Telli, den Brok & Cakiroglu, 2010). In particular, science teachers have been found to play an instrumental role in shaping students’ post-16 science-related choices in education and/or career (Sjaastad, 2012; Henriksen, Dillon & Ryder, 2015). This may be particularly the case for young people from under-represented and/or socially disadvantaged groups. For example, findings from surveys conducted with c.6,000 school students from ‘low participation’ backgrounds found that, comparing across a range of variables, the variable of the teacher’s input was most strongly related (i.e. showing the biggest effect size) with their perceptions of the utility of science (Archer, 2014). However, with the exception of a few studies that explore ways of theorising participation (Nasir & Hand, 2008) and extending science engagement beyond the classroom (Mallya, Mensah, Contento, Kock & Calabrese Barton, 2012), comparatively little is known about the nature and practical implementation of strategies and approaches that teachers might adopt to improve (increase and widen) student participation in science.

1  
2  
3 As discussed further below, perceptions and dispositions regarding the extrinsic value of  
4 science education form one of the eight dimensions of science capital. Indeed, research by the  
5 **Understanding Participation Rates in post-16 Mathematics And Physics (UPMAP)** project (Mujtaba &  
6 Reiss, 2014) shows that a student's perception of the extrinsic value of physics or maths is one of the  
7 strongest predictors of whether they plan to study the subject post-16. While a compelling case has  
8 been made for the value of highlighting the relevance and extrinsic value of science to students in order  
9 to increase science engagement and participation (Newton, 1988; Schreiner & Sjøberg, 2004; Claussen  
10 & Osborne, 2013), much less work has addressed how this might be done in practice. The current paper  
11 seeks to help fill this gap, by exploring how teachers (n = 10), representing a range of inner-city and  
12 suburban secondary schools, engaged with the concept of science capital and operationalised it in their  
13 practice.

### 23 **THEORISING SCIENCE CAPITAL**

24 The concept of science capital was originally developed in the ASPIRES *Young people's*  
25 *science and career aspirations, age 10-14*, research project to explain how a student's existing  
26 resources (notably their family's understanding of, and relationship to, science) can inform their post-  
27 compulsory education and career choices (e.g. ASPIRES 2013; Archer, Dewitt, Osborne, Dillon, Willis  
28 & Wong 2012). For instance, Archer *et al.* found that science capital has a strong relationship with  
29 student science aspirations and post-16 plans. In particular, a student from a family with medium or  
30 high science capital is more likely to plan to pursue science or STEM related qualifications and/or  
31 careers, whereas low science capital is associated with the expression of non-STEM aspirations (e.g.  
32 Archer *et al.*, 2012; Archer, Dewitt & Willis 2014; Archer, Dawson, Dewitt, Seakins & Wong 2015).  
33 The study reported here sought to further develop and to test the parameters and utility of science  
34 capital by studying the ways in which teachers, attending a year-long professional development  
35 programme, firstly made sense of the concept and thereafter operationalised it in their teaching.  
36  
37  
38  
39  
40  
41  
42

43 The concept of science capital derives from the Bourdieusian conceptualisation of 'capital'.  
44 The French sociologist Pierre Bourdieu (e.g. 1977, 1984, 1986) conceptualised capital as economic,  
45 cultural and social resources that can be used by those who possess them to produce social advantage  
46 within specific contexts. For Bourdieu, capital interacts with habitus (a person's internal matrix of  
47 dispositions, which are acquired through socialisation) within fields (i.e. across and within different  
48 contexts). Some commentators have likened capital to different types of skill and resource, akin to the  
49 'cards' (and knowledge of the 'rules') that a player might possess within a particular 'game' (field).  
50 The cards that a player has will shape their ability to play and their chances of 'winning' or 'losing'  
51 within a particular 'game' (Lareau & Horvat, 1999).  
52  
53  
54  
55

56 Bourdieu's conceptualisation of capital has been incredibly influential in sociology and  
57 education, but despite some development (e.g. Bennett, Savage, Silva, Warde, Gayo-Cal, & Wright  
58  
59  
60

2008), it was, and has remained, a predominantly arts-based conceptualisation, focusing for instance, on people's participation in *les beaux-arts*. Yet, as various commentators have noted, science qualifications arguably also command a high symbolic value within contemporary society. For example, research by Savage, Bagnall & Longhurst (2001) suggests that a person's chances of being in an elite social class are higher for those with a science degree than those with an arts degree. Hence the concept of science capital was developed to recognise how science-related cultural and social resources and practices also play a part in the re/production of social hierarchies of privilege or subordination.

As proposed by Archer *et al.*, (2015), the concept of 'science capital' contains a range of science-related resources, including cultural capital (which includes scientific literacy and scientific dispositions), science-related behaviours and practices, and science-related social capital (social contacts and relationships). It has been explained as:

A conceptual tool for understanding the production of classed patterns in the formation and production of children's science aspirations. We propose that 'science capital' is not a separate 'type' of capital but rather a conceptual device for collating various types of economic, social and cultural capital that specifically relate to science – notably those which have the potential to generate use or exchange value for individuals or groups to support and enhance their attainment, engagement and/or participation in science.

(Archer *et al.*, 2014: 5)

This conceptualisation has been developed through findings from empirical research. For instance, the ASPIRES study found that families with higher levels of science-related resources (science capital), are more likely to actively promote, develop and sustain their children's science interest and aspirations and are more likely to have children who plan to continue with science post-16 (Archer *et al.*, 2012). These families are more likely to provide children with science kits, watch science-related TV together, spend time discussing science in everyday conversations, and engage in science-related leisure activities, such as going to science museums.

The conceptualisation of science capital has since been further elaborated by Archer *et al.*, (2015), to explain how science capital combines three main forms of science-related capital (cultural capital; behaviours/practices; social capital), which can be distinguished into eight dimensions:

#### Science-related cultural capital

1. Scientific literacy (conceptualised broadly as scientific knowledge, skills, and an understanding of how science 'works' and the ability to use and apply these capabilities in daily life for personal and social benefit);
2. Scientific-related dispositions/preferences (such as the valuing of science in society);
3. Symbolic knowledge about the transferability of science in the labour market (knowledge about the extrinsic value and transferability of science qualifications);

### Science-related behaviours and practices

4. Consumption of science-related media;
5. Participation in out-of-school science learning contexts (e.g. visiting science museums, zoos/aquaria, going to science clubs etc.);

### Science-related forms of social capital

6. Family/parental scientific knowledge and qualifications;
7. Knowing people who work in science-related jobs;
8. Talking to others (outside school) in everyday life about science.

Although these dimensions are listed separately for presentational clarity, it should be noted that, in theoretical terms, we see them as interacting and overlapping aspects of science capital. The dimensions were formulated from analyses of data collected via a survey conducted in England with over 3,600 students aged 11-15 year olds (Archer *et al.*, 2015). The analysis indicates that possession of science capital is strongly patterned by social background, gender and set in science. Furthermore, students with high levels of science capital are much more likely than those with low science capital to plan to study science post-16 and record higher levels of confidence in their scientific abilities and are more likely to agree that others perceive them as a 'science person' (Archer *et al.*, 2015).

## **THE ENTERPRISING SCIENCE PROJECT**

The work reported here is part of a larger programme entitled Enterprising Science. This programme is a five-year partnership between King's College London and Science Museum, London funded by BP and involves research led interventions targeted at secondary students (aged 11–16), their teachers and families, with the ultimate aim of helping more young people find science engaging and useful. Building on the emergent interest in science capital, the Enterprising Science project offers a timely scoping exercise: a grounded attempt to refine and operationalise the concept by creating a science capital index and appropriate measuring tool (Archer *et al.*, 2015). Crucially, it seeks to forge new understandings about how science capital may best be nurtured and how science-capital building practices may best be implemented. Our work is founded on the belief that a theoretically and pragmatically developed concept will be useful for education researchers and practitioners (science teachers, educators, communicators and providers) alike.

## **THE TEACHER PROFESSIONAL DEVELOPMENT PROGRAMME**

The Teacher Professional Partnership Programme (TP3) is one strand of the Enterprising Science Project. It was explicitly named as such to acknowledge the expertise of teachers. Many professional

1  
2  
3 development programmes are predicated on the notion that teachers are somehow deficient and need  
4 developing (Webster-Wright, 2009). In contrast, we were keen to build on the practical expertise and  
5 experience of teachers in implementing classroom practices and to respond to their particular needs  
6 (Lumpe, Czerniak, Haney & Beltyukova, 2012). In addition to conceptualising the programme as a  
7 partnership, we also sought to develop a collaborative approach to the research element. Thus we  
8 hoped that teachers would be able to engage in actively studying their own practice by monitoring and  
9 reflecting on the effects of any change. Unfortunately, this ambition for the programme was not fully  
10 realised, mostly due to teachers feeling unable to collect the necessary data given conflicting pressures  
11 in their schools that limited their commitment.

12  
13  
14  
15  
16 As with all learners, teachers participating in a development programme do not arrive as blank  
17 slates. Rather, they have an abundance of prior experiences and expectations. Teachers also hold  
18 personal beliefs about the nature of learning and teaching (Borko and Putman, 1996; Calderhead,  
19 1996), and indeed the efficacy of their own practice (Cantrell and Callaway 2008). Moreover, some  
20 teachers may be open to learning new ideas, whilst others may feel that their practice is already  
21 sufficient (Haney, Czerniack & Lumpe, 1996). Glackin's (2012) work exploring the impact of teacher  
22 beliefs upon their behaviour, including their willingness to learn from a PD programme focussing on  
23 learning beyond the classroom, reminds us that the impact of any course will vary between individuals  
24 and that the significance of teacher beliefs, values and self-perceptions of efficacy should not be  
25 underestimated (see also Thomson and Gregory, 2013). Munby, Cunningham & Lock (2000)  
26 meanwhile, and more recently Allen and Penuel (2015) have highlighted the role played by wider  
27 contextual factors, such as school in-take, examination demands and curricular constraints, in shaping  
28 or altering the ways in which a teacher's expressed beliefs or understandings are enacted in practice.

29  
30  
31  
32  
33  
34  
35  
36  
37 In planning the programme we were conscious that theories of cognition and social interaction  
38 that apply to efforts directed at student learning should also apply to our endeavour. In particular we  
39 recognised the value of collaborative peer-to-peer learning (Loucks-Horsley, Hewson, Love, & Stiles  
40 1998; Brand & Moore, 2011). Thus we scheduled opportunities for teachers to work closely and  
41 collaboratively with their peers, with the university researchers and museum educators. Furthermore,  
42 we followed the argument of Nunnery (1998) and accepted that teacher ownership (and therefore  
43 application) of a new teaching approach does not necessarily mean that the teachers needed to invent it.  
44 Rather an individual may 'own' an approach if they have simply observed it working successfully in a  
45 setting [school] similar to their own.

46  
47  
48  
49  
50 The TP3 course design was also informed by reviews of best practice in teacher professional  
51 development. Following van Driel, Meirink, van Veen & Zwart's (2012) summary of key elements for  
52 success based on a review of 44 teacher PD studies, and Penuel, Fishman, Yamaguchi & Gallagher's  
53 (2007) survey of 454 teachers' implementation of PD, we sought to develop a programme that had a  
54 clear focus, was active, involved collaborative learning, was coherent, sustainable and was in accord  
55 with teachers' own local organisational issues. In partnering teachers to address their particular needs  
56  
57  
58  
59  
60

1  
2  
3 and to identify problems in their practice, we recognised the need for reflection (Brand & Moore,  
4 2011). However, we also noted that for reflection to be worthwhile it must, as Cobb, Zhao & Dean  
5 (2009) have argued, be tied to an action. In turn, such an action must be practically achievable in the  
6 context of the classroom leading to the solution becoming embedded in everyday practice. Palmer  
7 (2011) has suggested that by providing opportunities for teachers to reflect, act and practice, they gain  
8 'enactive mastery'. By additionally explaining the theoretical underpinnings of a process, teachers gain  
9 'cognitive mastery'. Thus we included theory-based presentations on the nature of science capital  
10 alongside opportunities to experiment with new ideas and resources.  
11

12  
13  
14  
15 The TP3 course was hosted by the partner museum over a period of 12 months, from June  
16 2013 to June 2014. It was delivered through one full day and seven twilight sessions with six to eight  
17 weeks between each session. It comprised 22 direct 'contact' hours - that is hours of PD sessions  
18 delivered by university and museum staff. The main focus of the course was 'careers from' science, i.e.  
19 building up awareness of the relevance of science skills in and beyond science, and of the  
20 transferability of science qualifications in the labour market. The task for each teacher, or pair of  
21 teachers if they came from the same school, was to develop classroom based practices, or teaching  
22 techniques, that would help students to see both the relevance of science in everyday life and the  
23 applicability of science to many varied careers.  
24

25  
26  
27  
28  
29 To help teachers think more broadly about possible developments to their classroom teaching,  
30 Science Museum staff showcased examples of museum-inspired activities. These activities embodied  
31 aspects of museum pedagogy – shorthand for the teaching and communication practices that take place  
32 in designed non-school settings that are rich with educationally framed real-world phenomena (Bell,  
33 Lewenstein, Shouse & Feder, 2009). The museum-inspired activities emphasised the role of both  
34 unusual and everyday objects in illustrating the contributions of science to cultural life. In showcasing  
35 exhibition techniques meanwhile, we hoped to instil a sense of wonder or excitement for science in  
36 participants and, in so doing, connote science as inherently interesting and valuable. The course also  
37 included presentations from King's College London staff outlining research around student  
38 [mis]perceptions of science, and student [mis]understandings of career options. These short  
39 presentations were embedded in the broader discussions around the theoretical concept of science  
40 capital. Teacher reflection was encouraged through the use of one-page reflection prompt sheets and  
41 the use of teacher portfolios (Orland-Barak, 2005) to document efforts and achievements.  
42

43  
44  
45  
46  
47  
48  
49 To support teachers outside of the PD programme, small groups of three or four teachers  
50 together with a university or museum member of staff were formed to facilitate on-going conversations  
51 and the sharing of ideas. The aim here was to ensure that the PD provided concrete support on how to  
52 develop teaching practices rather than simply provide theoretical input – a criticism commonly levied  
53 at PD initiatives (Garet, Porter, Desimone, Birman & Yoon, 2001). In addition, a series of social  
54 gatherings were arranged, including attendance at the Science Museum's late-opening events, with the  
55 aim of maintaining morale and engagement in the project.  
56  
57  
58  
59  
60

1  
2  
3 It was suggested that participants should spend between 15-20 hours of their own time  
4 preparing their teaching, implementing new practices in the classroom and reflecting on their  
5 effectiveness, although not all teachers committed this time. Thus, the total number of hours of the  
6 course including direct contact, group mentoring, independent and social hours, is hard to quantify and  
7 indeed varied from teacher to teacher. Nevertheless, the overall TP3 length accords well with the wider  
8 literature that notes that effective teacher professional development takes time (Darling-Hammond &  
9 Richardson, 2009; Joyce & Showers, 2002; Loucks-Horsley *et al.*, 1998; Yoon, Duncan, Lee, 2007). As  
10 Blank, de las Alas & Smith (2008) found, more than 50 hours of professional development are  
11 commonly reported as a prerequisite for positive impacts on student outcomes.  
12  
13  
14  
15

## 17 18 **THE STUDY**

19  
20 Our study sought to examine the experience of secondary science teachers engaged in a  
21 museum-hosted pilot professional development course, run as part of the wider Enterprising Science  
22 project, and aimed at supporting ways of building student science capital. Our research centred on  
23 exploring the extent to which teachers make sense of and thereafter operationalise the concept of  
24 science capital in their teaching. In other words we sought to examine the teachers' acquisition of both  
25 cognitive and enactive mastery (Palmer, 2011) with respect to science capital. We framed our  
26 investigation around two questions:  
27  
28  
29  
30  
31

- 32 1. How do teachers engaged in the PD programme understand the concept of science capital?
- 33
- 34 2. How do these same teachers operationalize science capital in the context of their classroom
- 35 practice?
- 36
- 37

38 This paper reports on findings from our investigation with a view to informing the on-going  
39 conceptualisation of science capital by incorporating the insights and experience of practitioners  
40 working with the concept. In this sense, the paper affords a theoretical input to science education  
41 research and also fulfils a wider aspect of the Enterprising Science project: understanding how the  
42 notion of science capital might be applied in practice.  
43  
44  
45  
46  
47  
48

## 49 **METHOD**

50 The research reported here comprises a qualitative case study of the TP3 PD programme run  
51 during the academic year 2013/14. Multiple cases of teacher informants contributed to a variety of  
52 sources of information (Yin, 1993) to provide a collective focus and to corroborate findings. This  
53 approach was chosen to broadly explore a contextual object/condition (Eisenhardt, 1989; Yin, 1993;  
54 Stake, 1998), that is, the phenomenon of TP3 as a means of building science capital. In this way,  
55  
56  
57  
58  
59  
60

1  
2  
3 theory may be developed from the case study as “a small step toward grand generalisation” (Stake,  
4 1998 p.91; Flyvbjerg, 2006) and meanwhile the case study allows novel, testable and empirically valid  
5 research through an analysis of themes (Creswell, 1998; Cohen, Manion & Morriison, 2000; Ehrich,  
6 2003).  
7  
8

9 The research, which received ethical approval from the University’s Research Ethics  
10 Committee, aimed to recruit between 15-20 teachers using the Science Museum’s established network  
11 of teachers in the recruitment process. 17 teachers started the course but only ten completed the PD in  
12 June 2014. All teachers participated voluntarily, (i.e. the TP3 was not part of compulsory training) and  
13 were free to cease their involvement at any time. The applicants represented a range of schools (some  
14 single-sex, some faith-based, some selective), and their schools reflected their local communities each  
15 with a range of socio-economic and ethnic backgrounds. The final purposive sample comprised 10  
16 teachers from across London and the outer suburbs. All participants were teaching with pupils aged  
17 between 11 and 14 in at least one of the following subjects: physics, chemistry, biology, and geography.  
18  
19  
20  
21  
22

23 The analysis of teacher conceptualisations of science capital draws mainly on interview data  
24 and field notes from the PD sessions. To analyse the operationalisation of the concept of science capital  
25 we assessed the quality of the pedagogical practices employed through a combination of classroom  
26 observations, PD fieldnotes, interviews and teacher portfolios. The teachers had neither the time nor  
27 the appropriate instruments to routinely or explicitly monitor the effects of any change in students as a  
28 result of their practice, but many kept anecdotal notes and subsequently shared their planning and  
29 examples of their students’ work. Consequently, the research data for this paper primarily draws on  
30 semi-structured in-depth interviews and classroom observations but is also complemented with teacher  
31 reflections and self-reports.  
32  
33  
34  
35  
36

37 The semi-structured, open-ended, one-to-one interviews with teachers were conducted prior to  
38 the course, at the midpoint and at the end of the course (Kvale, 2008). The initial interviews with  
39 course participants were conducted in May and early June 2013 prior to the introductory session in  
40 June where they met the team of museum educators and university researchers. The formal sessions  
41 commenced in the beginning of the following academic year in October 2013. The interview focused  
42 on teachers’ experiences and expectations (of teaching, PD, collaborative work and museums) and  
43 teacher beliefs (role as a teacher, science, careers from science) (Borko & Putnam, 1996; Loucks-  
44 Horsely *et al.*, 1998). Halfway through the course, in February 2014, the teachers were again  
45 interviewed to capture their emerging conceptualisations of science capital. Finally, post-interviews  
46 with teachers were conducted at the end of the programme in July 2014 and examined teacher  
47 conceptualisations of science capital, teacher beliefs about the value of science capital building  
48 pedagogy and teachers’ self-reports of their operationalization of science capital. All the pre, mid, post  
49 semi-structured interviews lasted between 30–60 minutes. All interviews were designed using Kvale’s  
50 (1996) three stage approach of a warm up, main body and cool off phase  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Observation fieldnotes (Emerson, Fretz, & Shaw, 2011) were recorded in classroom lessons in  
4 which new approaches were implemented, and at all PD sessions. Teacher accounts of their on-going  
5 efforts were elicited at these regular PD sessions and work completed by teachers with their students  
6 was shared. As noted above, teachers were also asked to keep a personal record of reflections – ‘a  
7 portfolio of evidence’ – to document their understanding and implementation of PD content (Regan,  
8 2013; Orland-Barak, 2005). At the end of the year, the teachers created posters summarising their  
9 activities and impressions. The posters were presented at two celebratory events, the first attended by  
10 project stakeholders and funders, and the second by fellow teachers at a late-opening evening event at  
11 the museum.  
12

13  
14 All interviews were digitally recorded, transcribed verbatim and anonymised by changing  
15 participants’ names and other relevant data to pseudonyms. Analysis of the data comprised qualitative  
16 thematic analysis (Braun & Clarke 2006), of interviews, fieldnotes and teachers’ own reflections  
17 (portfolios and posters). All data was read by at least two researchers who iteratively coded and  
18 recoded the responses using Braun and Clarke’s technique. Instances of teacher conceptualisation and  
19 teacher operationalization of science capital were coded against the eight dimensions described above  
20 and tabulated (see Table 1). Disagreements in coding were resolved through discussion between the  
21 authors and our wider research group. While we note that the analysis of interviews and fieldnotes  
22 from sample lessons may not capture the full extent of the teachers’ conceptualisation and  
23 operationalization of science capital, we argue that this process was appropriate for identifying which  
24 of our teachers appeared to have developed a stronger, or less strong, understanding of the principles,  
25 and the extent to which they had also been able to operationalize them. Our aim, therefore, was not to  
26 highlight deficiencies in teacher practice, but rather gain an insight into the ways that various  
27 individuals may make sense of the concept of science capital. Following the coding process, we  
28 identified three participants as broadly illustrative of the wider cohort’s experience. One teacher –  
29 Brian – had a strong conceptualisation of science capital and enacted this understanding in his practice.  
30 Lisa, on the other hand, had a clear understanding of the concept, but appeared to experience more  
31 difficulties in operationalizing the concept in her practice. Lastly, while Bernadette largely understood  
32 the concept of science capital, she appeared unable to put it into practice in her teaching. In short, the  
33 three teachers variously defined and operationalised science capital as the exemplar quotes  
34 demonstrate. Together, however, their accounts serve to create a broad but nuanced picture of teacher  
35 learning and practice as facilitated by the PD course.

## 51 FINDINGS

52 As explained above, the aim of the study was not to evaluate the PD course per se, but rather  
53 focus on ways in which teachers made sense of the concepts presented. It is nevertheless worth  
54 mentioning, as noted in the pilot year feedback report (King & Nomikou, 2014), that, overall, the  
55 teachers found the course to be enjoyable and worthwhile. In particular, participants acknowledged the  
56  
57  
58  
59  
60

1  
2  
3 extended duration and the opportunity to work with peers as positive elements of the course. They  
4 particularly enjoyed meeting in the Science Museum and saw it as an opportunity for learning in a new  
5 and inspiring environment, which simultaneously conferred a degree of authority and uniqueness to the  
6 proceedings. They also valued the academic input from the university partner noting the added rigour  
7 and increased credibility of the learning experience. Participants' rich appreciation of the PD provides a  
8 notable context for the findings presented below. We turn now to a more detailed analysis of the extent  
9 to which teachers conceptualised, and thereafter operationalised, science capital.

10  
11  
12  
13  
14 When asked to give a definition of science capital, teachers were arguably comprehensive in  
15 their accounts as the following quotes exemplify:

16  
17  
18 *It's their parents, the books they read, you know, if they watch TV programmes, which*  
19 *might be David Attenborough or whatever ... you know, all of the different things which*  
20 *might influence their life that might have a scientific background – that's what I think of as*  
21 *science capital. (Anthony, post-interview)*  
22

23  
24 *It's the amount of science that pupils come into contact with outside of the classroom.*  
25 *Whether it be the amount of science that their parents have, the amount of talk at the*  
26 *dinner table, the amount that they're able to relate normal things to science. (Michelle*  
27 *post-interview)*  
28

29  
30 Indeed all the teachers articulated their understanding of science capital by invoking at least four  
31 of the eight dimensions. Table 1 presents a summary of the teachers' views and practices. All names  
32 are pseudonyms.  
33

34  
35  
36 - Insert table 1 about here -  
37

38  
39 As can be seen from Table 1, all teachers conceptualised science capital as comprising science-  
40 related dispositions and attitudes, and all nine also sought to find ways to address this in their practice.  
41 Most did this by trying to emphasise the relevance of science to everyday life:  
42

43  
44  
45 *[I will seek to be] spreading the discussion about the relevance of science in everyday life*  
46 *beyond a single lesson. In particular, I'd like to run this discussion with Y8 and Y9*  
47 *students ahead of their subject choices. (Harini – poster)*  
48

49  
50 *I sought to address low engagement with my Y10 bottom set by explicitly linking science*  
51 *concepts with their lives/interests. In this way I was able to highlight the relevance of the*  
52 *lesson content. (Anthony – poster)*  
53

54 Most teachers (8/9) also saw science capital as comprising students' out of school science  
55 activities, although only three attempted to find ways to address or facilitate this through specific  
56 techniques. Notably, teachers used the term 'out of school' in this instance referring to not necessarily  
57  
58  
59  
60

1  
2  
3 out of school time but outside of the physical school environment. All three teachers who  
4 operationalised 'out of school' did so through visits to museums (but still during school time).  
5

6 Most teachers (6/9) saw science capital as comprising scientific literacy. Seven out of nine  
7 (including two who did not include scientific literacy in their SC conceptualisation) also sought to  
8 build elements of scientific literacy in their activities:  
9

10  
11  
12 *We developed a lesson structure that built on the skills and techniques learnt in TP3*  
13 *[lesson starters using images] ... The format can be applied to standard lesson plans so*  
14 *teachers are able to quickly assess the available resources and more easily engage and*  
15 *enthuse their class. (Ajay - poster)*  
16

17 The same proportions (6/9) of teachers conceptualised science capital in terms of knowledge  
18 about the transferability of science skills, science-related social capital (knowing someone who works  
19 in a science job), and parental science knowledge/ qualifications. However, fewer teachers sought to  
20 operationalise these three dimensions in their teaching (4/9, 2/9 and 4/9 respectively). One of the least-  
21 cited (n = 3) conceptualisation of science capital was the dimension of talking about science with  
22 others in everyday life, although interestingly, this dimension was operationalized to a greater degree (n  
23 = 5) suggesting that the teachers implicitly recognised its value, but did not appear to explicitly  
24 conceptualise it thus.  
25  
26

27  
28  
29 We note that in summarising the teachers' conceptualisations and operationalisations in a  
30 simple binary approach of present, or not, does not provide any indication of depth of understanding, or  
31 quality of practice. Nonetheless, the table provides a useful top-level summary of the experiences of a  
32 group of teachers and highlights the general areas in which the understanding and operationalisation of  
33 science capital was achieved to either a greater or lesser degree.  
34  
35

36  
37 The teachers' focus on developing positive attitudes towards science, and enhancing science  
38 literacy is perhaps not surprising. After all, such emphases reflect what teachers commonly do and are  
39 good at. However, such a finding has important implications for efforts in supporting science capital  
40 across all eight dimensions; clearly teachers intuitively find dimensions 3–8 to be harder to  
41 operationalise. In addition, and is clear from the table, the degree of alignment between the teachers'  
42 conceptualisation and operationalisation for dimensions 3–8 varies markedly. In the vignettes below we  
43 discuss possible reasons teachers' ease or difficulty in conceptualising and operationalizing aspects of  
44 science capital.  
45  
46  
47  
48

### 49 **The Case of Brian**

50  
51 Brian has 11 years teaching experience and is now Head of Science in a boys' comprehensive  
52 school in an area of London with relatively high levels of deprivation. Brian is highly committed to  
53 raising standards in and uptake of science courses. He regularly communicates with his students'  
54 parents and has recently begun using Twitter to promote the activities of the science department. He  
55  
56  
57  
58  
59  
60

1  
2  
3 notes, however, that parental support of their sons' science learning is very mixed. He regularly attends  
4 professional development courses and welcomes opportunities to enhance his practice.

#### 5 6 *Conceptualisation*

7  
8 In defining science capital, Brian offered a broad depiction that encompassed a number of  
9 science capital dimensions including knowledge, attitudes, qualifications and everyday practices  
10 such as science media consumption. In seeking to capture the impact of this spread of knowledge  
11 from across broad experiences Brian used the metaphor of science capital being one's 'science  
12 baggage':  
13  
14

15  
16  
17 *Oh gosh ... science capital is the background science that a student or a family come to*  
18 *you with. That's sort of my understanding of it. So it's their experiences of science ... to*  
19 *date almost really ... whether it is to do with new television, other media, their*  
20 *qualifications ... it's sort of their science baggage.*

21 (Brian post-interview)

22  
23  
24 Like many of the teachers, Brian felt that the concept of science capital 'made sense' and  
25 resonated with his own instincts and professional experiences. He noted that that the concept served to  
26 articulate something that he intuitively felt but was unable to name. Brian may have found the concept  
27 to be particularly relevant as it accords well with his on-going efforts to engage parents in their sons'  
28 education. As Luke and McCreedy (2012) have argued, citing the work of Cox (2005), Christenson and  
29 Sheridan, (2001) and Fishel & Ramirez (2005), when parents and schools work in conjunction,  
30 students tend to engage more with the learning focus promoted by of school. When this focus involves  
31 building capital for students to utilise both in and beyond school, the value of involving parents  
32 becomes increasingly apparent.  
33  
34  
35  
36

#### 37 *Operationalization*

38  
39 Brian's understanding of science capital as distributed across a student's life experiences, from  
40 home and into school, led him to find ways to make science part of the student's everyday life, by  
41 prompting everyday science conversations between students and their parents as a means to start  
42 integrating science within the daily fabric of family life and interaction (addressing science capital  
43 dimensions 8 and 2). Brian's operationalisation can thus be viewed as an attempt to influence *family*  
44 *habitus*, 'the collective cognitive matrix of dispositions which produces a family's sense of "who we  
45 are", "what we value" and "what is normal for us" (Archer *et al.*, 2012):  
46  
47  
48  
49  
50

51 *What we're trying to do is get parents to be interested in science so that they have a*  
52 *conversation with their children about science ... or the other way round, that the children*  
53 *can be going and having a conversation with their parents and saying 'Look at this' ....*

54 (Brian, mid-interview)

55  
56 Brian acknowledged the need to generate interest in order to promote conversations. Thus he  
57 developed a website and series of 'conversation cards' showcasing the science qualifications and  
58  
59  
60

1  
2  
3 achievements of well-known celebrities (actors, sportspeople, TV presenters). His aim was to use the  
4 resources to prompt classroom discussions about the value of science for all sorts of future careers. In  
5 particular he sought to demonstrate, through what he described as ‘celebrity endorsement’, that science  
6 is a credible subject.  
7  
8

9 When reflecting on the success of this approach, Brian noted that the resources on their own  
10 were not enough to generate on-going conversations that would automatically spread back to the home.  
11 Whilst the students were clearly intrigued by the celebrities’ varied science histories, without teacher  
12 support they lacked the skills to engage in deep or on-going discussions. In noting this limitation, Brian  
13 identified that science capital is not a discrete skill or ‘thing’ that can be promoted through a single  
14 activity, but moreover is an individual’s resource which may be enriched and developed by careful  
15 nurturing such as through the facilitation of science teachers.  
16  
17  
18  
19

20 From a personal perspective, Brian found the PD course to be beneficial in terms of  
21 building self-confidence and self-efficacy as a teacher of science. For example, the realisation that  
22 there is a concept that encapsulates his feelings about teaching, and moreover one that has been  
23 theoretically and empirically substantiated, enabled Brian to legitimate his practice. It gave him the  
24 firepower to defend his practices and principles at school (with senior manager/colleagues):  
25  
26  
27  
28

29 *I think it’s legitimised what sometimes I didn’t realise that we should be doing, but felt as*  
30 *though it was the right thing to do. And now actually we’ve got ammunition to be able to*  
31 *say yes it is the right thing to do.*

32 (Brian, post-interview)  
33

34 However, whilst Brian appeared to understand the value of raising science capital, he doubted  
35 whether he would be able to spread this understanding and concomitant approaches more widely:  
36  
37

38 *I think the difficulty is getting the rest of my team to include it as well. Because it’s all well*  
39 *and good saying in their scheme of work on in a lesson ‘please talk about this now’ but if*  
40 *they haven’t got the knowledge to be able to just talk about it easily, it’s going to be*  
41 *difficult.*  
42

43 (Brian, post-interview)  
44

45 Brian’s admission of the limited extent to which any new practices will be embedded is  
46 perturbing given his position of Head of Science and thus his ability to influence his team’s work.  
47 However, it should be noted that as with all new ideas and practices, unless the individual colleague  
48 understands them and thereafter regards them to be fruitful and more plausible than previously held  
49 ideas (Posner, Strike, Hewson & Gertzog, 1982), they are unlikely to adopt or operationalise them in  
50 their practice.  
51  
52

59  
60

### The Case of Lisa

Lisa has been teaching in the UK for 11 years. She is currently in a school where nearly half of the students have free school meals, and the ethnic mix is very broad. Whilst the school has fared well under previous Ofsted<sup>1</sup> inspections, a recent external review has identified the science department as needing to improve student engagement. Lisa experiences few opportunities to engage with colleagues or to think creatively in her everyday teaching. She enrolled on the PD course as she is keen to strengthen her teaching skills and wants to be reinvigorated in her chosen career.

#### *Conceptualisation*

Lisa described science capital as an embodiment of whom you know and what you know. However, she also saw it as a means to an end, rather than a resource that could be utilised. Thus she defines it not so much as a perspective on society wherein one sees and is able to access the inherent value of science, but more as a device or vehicle that teachers could use to encourage more young people to be interested in science:

*I would say having immediate links to scientific projects or activities, or people in a scientific type career and get information about scientific careers and ... yeah, people that they can go to; activities that they could get them interested more into the sciences.*

(Lisa post-interview)

Throughout the course Lisa expressed the concern that although she found science capital a compelling concept when someone explained it to her, she had difficulty in 'fully understanding it'. This may explain her somewhat piecemeal conceptualisation and subsequent operationalisation of the term.

#### *Operationalization*

In developing her practice, Lisa sought to emphasise the relevance of science in everyday life by using images as a regular feature of her lessons:

*I wanted to expose students to a variety of images that could be considered scientific, hoping that over time would begin to see how scientific ideas are part of their everyday life.*

(Lisa's poster)

The images included cartoons, adverts and pictures of both strange and everyday objects. The images were introduced at the beginning of every lesson as a 'starter' activity and were accompanied with one or two questions that prompted student thinking and discussion. Over time, Lisa reported that students were questioning the information in the images more intensely, and that more and more students felt comfortable engaging in debates about the topic, and appeared to recognise the place and relevance of science across all aspects of society (dimension 2).

Whilst clearly effective in generating student interest and understanding of the relevance of science, Lisa's practice did not fully match with her conceptualisation of science capital. The emphasis

1  
2  
3 in her teaching was primarily placed on generating interest: it did not extend to discussing the range  
4 and variety of jobs that might relate to the images on display (dimension 3), nor did Lisa explicitly seek  
5 to build students' science capital by building on parental knowledge and qualifications (dimension 6) or  
6 by helping students to meet, or recognise that they already know, somebody in a science-related job  
7 (dimension 7). Perhaps the reason for this mismatch was Lisa's acknowledged lack of confidence in  
8 talking about careers from science. When asked how she might help convey to students the  
9 transferability of science skills to the wider market (dimension 3) Lisa explained that she did not have  
10 the knowledge, and moreover saw this as the responsibility of the school's 'careers person':  
11  
12  
13  
14  
15

16  
17 *I do find it hard. I can relate the skills as long as I know about the career. But it's like*  
18 *harder for me to tell you beyond doctor, veterinary and all those kinds of like careers, as*  
19 *to what are the other careers beyond that need science.*

20 (Lisa post-interview)

21  
22 Lisa's comments were echoed by several of the other teachers who similarly saw their roles as  
23 simply 'deliverers' (of science content) and 'enthusers' (promoting student interest in science). Whilst  
24 they acknowledged the scope of science capital as stretching from home to school, they did not  
25 consider it their responsibility to address aspects beyond scientific literacy (dimension 1) and  
26 dispositions (dimension 2). Indeed, whilst they saw their roles to comprise teaching students in the  
27 classroom and would do that as imaginatively as possible, they did not think that they had any  
28 responsibility for what happens to students beyond the classroom. This view was exacerbated by the  
29 daily pressures that teachers are under to deliver on attainment targets. As Lisa explained:  
30  
31  
32  
33  
34

35 *When the exams are kind of bearing down on us, we kind of forget real life, cos we just*  
36 *don't have enough time to kind of do extension work.*

37 (Lisa post-interview)

38  
39 For Lisa, the collegial nature of the PD was an extremely positive experience. She had  
40 welcomed the chance to learn from and share with other teachers. She noted that in her own school  
41 there were few opportunities to work collaboratively with colleagues to develop her teaching. As a  
42 consequence, the possibility for Lisa to embed her new practices within her department or school more  
43 widely, let alone to continue developing her personal understanding and operationalization of science  
44 capital, would appear to be limited.  
45  
46  
47  
48

#### 49 **The Case of Bernadette**

50 Bernadette has been teaching for eight years, all in the same school that includes a high  
51 number of students with English as an additional language. Furthermore, the school experiences high  
52 'mobility' with many students arriving or leaving the school mid-term. The school has only recently  
53 come out of 'special measures'<sup>2</sup> status following an increase in student attainment scores. Science in  
54 the school has not always fared well, with few students achieving well or choosing to continue science  
55 post-16. Bernadette welcomed the chance to gain new ideas for her teaching, and was drawn to the  
56  
57  
58  
59  
60

1  
2  
3 museum-hosted PD course in particular as she hoped that this would lead to opportunities for her  
4 students to experience new environments and thus broaden their horizons.

#### 5 6 *Conceptualisation*

7  
8 From the outset of the course, Bernadette had acknowledged the value of exposing students to  
9 wider experiences. Like Brian, she welcomed the concept of science capital as defining something she  
10 had already recognised in her students. Indeed, Bernadette regularly used the term science capital  
11 unprompted, and moreover cited the need to raise science capital amongst her students in her final  
12 interview as the justification for applying to the course. When asked to define science capital,  
13 Bernadette offered the following:  
14

15  
16  
17  
18 *Science capital is ... as I said, it's background knowledge and experience, but background*  
19 *knowledge and experience that comes from others, as well as what they experience in their*  
20 *day to day life. It's related to their home lives as well as their backgrounds, but it's to do*  
21 *with what other experience ... what direct or indirect experience of science they have in*  
22 *terms of their family, in terms of friends and backgrounds, rather than what they get from*  
23 *school....*

24  
25 (Bernadette, post-interview)

26  
27 This conceptualisation is clearly very broad, and encapsulates the distributed nature of  
28 science-related knowledge and experiences a student might have. However, it does not capture the  
29 sense of science capital being a resource to be utilised.

#### 30 31 *Operationalisation*

32  
33 Bernadette appeared to operationalise science capital as an effort to reduce inequity. For  
34 example, she spoke at length about the value of providing students with experiences that might broaden  
35 their aspirations/ horizons and encourage social mobility:  
36

37  
38  
39 *I think just, I mean, even in terms of our students, taking the tube to go to the museum, you*  
40 *know, from something as basic as that, to leaving the area and going somewhere else and*  
41 *seeing that these places exist and especially where the Science Museum is, right next to*  
42 *Imperial [College, London]. It kind of starts them questioning and starts them thinking*  
43 *about further education and oh, you know, okay, well, maybe one day I'd like to go to*  
44 *Imperial.*

45  
46 (Bernadette, post-interview)

47  
48 However, in developing an approach, Bernadette's initial emphasis on providing life  
49 experiences did not materialise. Instead, Bernadette's recognition of the students' language difficulties  
50 as new migrants, together with her personal passion for supporting home influences led her to develop  
51 an activity in which students were encouraged to explore every day and more unusual objects in  
52 lessons and thereafter talk about these objects with their parents for homework. Thus one homework  
53 task was set as: 'with the help of a parent or older family member, how many objects can you list that  
54 fit into your pocket today, but would not have done 20 years ago?' In this way, Bernadette's approach  
55  
56  
57  
58  
59  
60

1  
2  
3 promoted science literacy skills (dimension 1) and positive dispositions towards science (dimension 2),  
4 and also encouraged students to talk about science outside of the school context (dimension 8).  
5

6 When asked about plans for sharing her understanding of the concept of science capital more  
7 widely with colleagues, Bernadette noted that the colleagues were already engaged in efforts to bridge  
8 the gap between those students that have and those that don't have science capital:  
9

10  
11  
12 *What we're trying to do is to build on that to kind of bridge the gap between those people*  
13 *who don't have input from home and background capital, so that we can kind of catch*  
14 *them up to the other people who do have the science capital background.*

15  
16 (Bernadette post-interview)

17  
18 However, Bernadette also commented that it would be difficult to substantively change any  
19 practice in the school that might be perceived to detract from the school-wide focus on attainment.  
20 In this regard, Bernadette's experience resembled several of the teachers who cited similar  
21 constraints in embedding science capital approaches more broadly within their departments/  
22 schools.  
23  
24  
25  
26  
27

## 28 **DISCUSSION AND IMPLICATIONS**

29  
30 Our findings suggest that the concept of science capital resonated with the teachers involved in the PD  
31 course, although there was considerable variability in the ways in which they conceptualised and  
32 operationalised science capital in their practice. Indeed, we found that a teacher's conceptualisation of  
33 science capital did not necessarily concur with the extent of their subsequent operationalisation. In  
34 other words, whilst teachers may have gained cognitive mastery in understanding the concept, and felt  
35 that it resonated with their own experiences, this did not mean that they necessarily gained enactive  
36 mastery and thus became able to fully realise the concept in their pedagogical practice (Palmer, 2011).  
37 In some instances, for example for Elle, this may be due to her ardent belief that her practice was  
38 already sufficient (Haney *et al.* 1996). For others, for example Bernadette, the wider contextual  
39 pressures of the school's recent Ofsted rating and subsequent pressures to increase examination scores  
40 may have adversely impacted her ability to fully enact her understanding (Munby *et al.* 2000; Allen &  
41 Penuel, 2014).  
42  
43  
44  
45  
46  
47

48 We found that science-related dispositions (dimension 2) and scientific literacy (dimension 1)  
49 were the most commonly conceptualised and addressed aspects of science capital. For many of our  
50 teachers, the dimension of science-related dispositions was almost synonymous with the notion of  
51 relevance of science in (students') everyday life, while our academic conceptualisation of dimension 2  
52 is more nuanced and includes attitudes to science and scientists, views of school science, and a  
53 supportive (family) environment towards science education (Archer *et al.*, 2015). It was also notable  
54 that teachers felt generally less confident addressing areas such as students' consumption of science  
55  
56  
57  
58  
59  
60

1  
2  
3 related media (dimension 4), participation in out of school learning contexts (dimension 5) and  
4 knowing someone in a science-related job (dimension 7).  
5

6 These findings provide some useful pointers regarding how we might improve the ways in  
7 which we work with teachers in PD courses and elsewhere to communicate the concept of science  
8 capital, with respect to both the breadth of the concept, and also in terms of developing approaches that  
9 might address a wider range of science capital dimensions. These insights may also be particularly  
10 useful in terms of developing and honing public engagement and communication activities to support  
11 participation in science from young people of all backgrounds. Indeed, we have noted that, beyond  
12 academia, the concept of science capital seems to be gaining traction within the policy and STEM  
13 education delivery sphere, and is becoming prominent within the discourse and activities of a range of  
14 STEM organisations in UK and beyond.<sup>3</sup> In particular, the findings discussed in this paper suggest that  
15 more thought might be usefully given to ‘translating’ the breadth of the concept to ensure that it is not  
16 reduced to one or two dimensions within policy enactment.  
17  
18  
19  
20  
21  
22

23 The variance in terms of how teachers conceptualised science capital versus the extent to  
24 which they were able to operationalise it is, perhaps, to be expected. The PD programme was after all  
25 in its pilot year and as a result, the course may not have included enough opportunities for teachers to  
26 fully understand the breadth and nature of science capital as a resource, and thereafter consciously  
27 translate their understandings into concrete actions. Indeed, as Rokeach (1968) noted, beliefs that are  
28 held as core – for example one’s perception of what constitutes effective teaching practice – are hard to  
29 change. As a consequence behaviours will also remain fixed. The aim here, then, becomes one of  
30 supporting teachers to embrace science capital as a concept and to see the ways in which it aligns with  
31 and enriches their current practice. Furthermore, if science capital is more confidently articulated by  
32 teachers, it will become part of their everyday vocabulary and as such will become a useful common  
33 denominator term for teachers to describe the important aspects of the work that they do, and share this  
34 with colleagues across school. In addition, by sharing their conceptualisations of science capital  
35 teachers are afforded with the opportunities to reflect on their beliefs about the purpose of science  
36 teaching and in turn improve their practice (Bell & Gilbert, 1994; Darling-Hammond & Richardson,  
37 2009). However, whilst a full articulation is ideal, more pragmatically, and in terms of designing future  
38 PD programmes, it may be more appropriate to focus on changing practice across just one or two  
39 dimensions. Indeed, the focus for the professional development programme for 2015 was centred on  
40 approaches that link home and school by building on family ‘funds of knowledge’ (Moll, Amanti, Neff  
41 & Gonzalez, 1992) and extending science participation activities into the home or community. A  
42 second study documenting the efficacy of this approach is ongoing.  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52

53 In line with other findings examining the effect of PD programmes (Garet et al, 2001; Penuel  
54 et al, 2007) our analyses suggest that there are a number of factors affecting the operationalisation of  
55 science capital in the classroom context. Firstly, science capital is a somewhat complex concept and  
56 some of the nuance may, inevitably, get ‘lost in translation’. For instance, we proposed the concept as  
57  
58  
59  
60

1  
2  
3 requiring a shift in pedagogy, rather than being deliverable through a single, simple activity or resource  
4 (hence the desire to work with teachers through an extended PD course). This inevitably requires an  
5 investment of time and resource by both deliverers and participants – and may be inherently less  
6 appealing to many hard-pressed teachers as compared to some existing ‘one size fits all’,  
7 single/discrete activity approaches for increasing student engagement with science. No teacher reduced  
8 the concept to a single dimension, but several (for example, Elle) limited their approaches (particularly  
9 in terms of operationalising the concept) to focusing primarily on scientific literacy and dispositions.  
10  
11

12  
13 Secondly, and relatedly, implementation of science-capital building approaches may be  
14 hampered in practice by the constraining context within which many teachers work (Munby, *et al.*,  
15 2000; Allen & Penuel, 2014). For example, the demands of the current teaching context may have  
16 played a part, in shaping teachers’ expectations and motivations, constraining their available time, and  
17 raising the ‘risk’ of trying something ‘different’. As Lisa explained in her earlier quote, the pressure of  
18 ‘exams’ (and the pressure to achieve attainment targets) can mean little time or justification for  
19 engaging in (anything defined as being) non-core (‘extension’) activities. In this respect, we suggest  
20 that efforts to build student science capital through science teaching will need to recognise that  
21 implementation will not be straightforward and that teachers will need considerable support to engage  
22 with the concept if they are to also change their beliefs and practice to better promote and build science  
23 capital among their students. The task for proponents of a science capital approach (including designers  
24 of PD courses) will be to develop more accessible and tangible ways for teachers to firstly grasp the  
25 concept and then to review their personal beliefs about the purpose of science teaching.  
26  
27

28  
29 Thirdly, and further relating to the strength of existing beliefs, some teachers appear to see  
30 particular dimensions of science capital as being ‘beyond their remit’ as science teachers. Our findings  
31 suggest that dimension 3 (symbolic knowledge about the transferability of science) may need particular  
32 care in this respect. As research by the ASPIRES and UPMAP projects shows, and as forcibly argued  
33 by Claussen and Osborne (2013), this is a particularly important and influential dimension within  
34 science capital which schools could (and should) usefully convey. Yet, as our data suggests, generally  
35 teachers do not feel well equipped or well placed to address this dimension within their everyday  
36 teaching. As Lisa put it earlier, for her, this would be the responsibility of the school’s ‘careers person’.  
37 In other words, some teachers may not necessarily believe it to be their responsibility to build science  
38 capital for the student’s benefit beyond the classroom. We thus suggest that advocacy work and further  
39 research may be necessary to build and strengthen the case as to why this would fit within a science  
40 teacher’s existing remit. A promising avenue in this respect is provided by the US Careerstart project  
41 (Woolley, Rose, Orthner, Akos & Jones-Sanpei 2012). Arguably, a considerable shift in teacher  
42 expectations and practice is still required in order to implement such an approach, although the gains in  
43 motivation, attendance and attainment in mathematics recorded by Woolley *et al.*, (2012) in relation to  
44 the Careerstart intervention with middle-school students, suggests that there may be possibilities for  
45

1  
2  
3 showing the mutual alignment of science capital building aims with the demands of the high stakes,  
4 attainment and target-focused education system that most science teachers must operate within.  
5

6 Fourthly, it is difficult for one individual teacher to fully operationalise new ways of thinking if  
7 colleagues are not similarly adopting such approaches (Bell & Gilbert, 1994; Guskey, 2000). As the  
8 literature suggests, support from senior management can be essential for ensuring that new practices  
9 and approaches are embedded within everyday teaching. As several teachers noted, senior management  
10 hold considerable sway in dictating an individual teacher's classroom practice. As such, the challenge  
11 for advocates of science capital building approaches will be to find ways to effect culture change  
12 within science departments and ensure senior manager buy-in. If this does not occur, the efforts of  
13 individual teachers are likely to remain isolated and transient.  
14  
15

16 Finally, the challenge for science capital proponents will be to find more tangible and credible  
17 ways to measure the outcomes of science-capital building approaches and the outcomes for students.  
18 This is an area of work that we are already currently developing (Archer *et al.*, 2015) but which will be  
19 of particular significance if a case is to be made for the utility of integrating a science capital approach  
20 into mainstream science teaching and on-going professional development. This present paper reports  
21 on an exploratory pilot PD course conducted with a small number of teachers, in which the aim was to  
22 understand teachers' conceptualisation of science capital and to explore and co-develop some potential  
23 approaches for building science capital within their teaching. Hence we did not attempt to collect any  
24 'hard' measures of the outcomes on students. Yet clearly, attempts to advocate for the efficacy of such  
25 an approach will require the ability to show positive outcomes for students (and teachers).  
26  
27

28 Several teachers on the course intimated that they had noticed a difference in their students, but  
29 these accounts were anecdotal (and hence have not been reported as data within this paper).  
30 Furthermore, when asked how they might document the changes in their students, most teachers were  
31 unable to identify any appropriate mechanisms. To address this problem, our research team is currently  
32 developing a statistically validated standardized measure that can document student gains in science  
33 capital over time or as a result of a targeted intervention (Archer *et al.*, 2015). We hope that future work  
34 will report on the outcomes for students following the implementation of teaching approaches  
35 developed by our next wave of teachers attending the PD programme.  
36  
37

38 The key contribution of this paper lies in the application of the theoretical and analytic lens of  
39 science capital to teacher practice. The findings highlight both the possibilities and the difficulties  
40 faced by teachers in gaining enactive mastery to operationalise science capital. We find it encouraging  
41 that the teachers found the concept to be compelling and to resonate with their intuitive experiences.  
42 Our focus next will be on ways of further supporting teachers to operationalise science capital with the  
43 aim of using these experiences to leverage change at the level of curriculum and school policy and  
44 finding ways to measure the outcomes for students and teachers. Finally we note that our efforts  
45 contribute to the growing body of work on-going around the world that seek to support and understand  
46 student engagement and participation in science (Reiss, Hoyles, Mutjaba, Riazi-Farзад, Rodd, Simon  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 & Stylianidou 2011; Gilbert, Lewenstein & Stocklmayer, 2013; Tan & Calabrese Barton, 2012). That  
4 is, we hope that a better understanding of teachers' engagement with and operationalisation of the  
5 concept of science capital will enable us to develop more effective approaches for building student  
6 science capital that can contribute to efforts to enhance student engagement (and ultimately improve  
7 their participation) in science. As one teacher aptly concluded:  
8  
9

10  
11  
12 *It does sometime seem like an insurmountable thing but, you know, you just have to*  
13 *remember that it's not just going to be one approach that changes this, it's going to be*  
14 *many varied approaches that will have an impact.*

13  
14 <sup>1</sup> Ofsted is the government Office for Standards in Education, Children's Services and Skills in England. They  
15 inspect and regulate services that care for children and young people, and services providing education and skills  
16 for learners of all ages

17 <sup>2</sup> 'Special measures' is a status applied by regulators of public services in Britain to providers who fall short of  
18 acceptable standards. A school subject to special measures will have regular short-notice Ofsted inspections to  
19 monitor its improvement. The senior managers and teaching staff can be dismissed and the school governors  
20 replaced by an appointed executive committee. If poor performance continues the school may be close.

**Table 1: Summary mapping of teachers' conceptualisations and operationalisation of the concept of science capital**

	Science-related cultural capital			Science-related behaviours and practices		Science-related social capital			
	1. Scientific literacy	2. Scientific-related dispositions	3. Knowledge about the transferability of science in the labour market	4. Consumption of science-related media	5. Participation in out-of-school learning contexts	6. Family/parental science knowledge and qualifications	7. Knowing people who work in science-related jobs	8. Talking to others about science

---

<sup>i</sup> Ten teachers completed the PD course, but nine are reported in the table. For the purposes of our analysis we regard Michelle’s and Jo’s answers as coming from one teacher: they were from the same school and planned and delivered all activities as a team. Moreover, their individual responses regarding conceptualisation of SC did not differentiate, i.e. they both referred to the same SC dimensions
