Abstract

Work plays a crucial role in rising social inequalities, which refer to unequal opportunities and rewards for different social groups. Whereas the conventional view of workplaces as meritocracies suggests that work is a conduit for social equality, we unveil the ways in which workplaces contribute to the accumulation of social inequality. In our cumulative social inequality in workplaces (CSI-W) model, we outline how initial differences in opportunities and rewards shape performance and/or subsequent opportunities and rewards, such that those who receive more initial opportunities and rewards tend to receive even more over time. These cumulative social inequality dynamics take place via nine different mechanisms spanning four different levels (individual, dyadic, network, and organizational). The CSI-W indicates that the mechanisms interact, such that the social inequality dynamics in workplaces tend to (a) exacerbate social inequalities

Alice Cooper—Lost in America

In September 2015, the United Nations adopted a set of 17 global goals to end poverty, protect the planet, and ensure prosperity for all (United Nations, 2018). Two of these goals (Goal 5: gender equality and Goal 10: reduced inequality) involve diminishing social inequality, which refers to group-based differences in opportunities and rewards. In capitalist societies, workplaces are considered to be the major vehicles for achieving these goals. In line with the ideal of the “American Dream,” workplaces are believed to represent meritocratic environments where workers, regardless of their background, can overcome any deprived situation they may find themselves in. By offering opportunities and rewards based on workers’ contributions, workplaces are expected to dissolve initial inequalities in opportunities and rewards, thereby enabling social mobility and reducing or breaking broad societal patterns of stratification (Pitesa & Pillutla, 2019).

This view of workplaces as meritocracies has been challenged by numerous studies indicating that in many workplaces, employees continue to be treated differently depending on their social group membership (e.g., gender, age, ethnicity, and socioeconomic background) (Acker, 2006; Hirsh, 2009; Merluzzi & Sterling, 2017; Pitesa & Pillutla, 2019; Rubery & Grimshaw, 2015). Such studies have shown that, for example, job applicants with an Arabic name are less likely to be selected compared to

equally qualified job applicants with a Western name (Sawert, 2019), that women are held to stricter performance standards than equally performing men (Foschi, 1996), and that older workers are given poorer performance evaluations than equally performing younger workers (Bal et al., 2011). These studies suggest that instead of being meritocracies, workplaces tend to be mirrors of society where social inequality continues to persist.

Research on inequalities in society, however, suggests that there is a third, even grimmer perspective on the role of workplaces in addressing social inequalities. According to this cumulative advantage perspective, initial inequalities increase over time because workers with an initial advantage have increasing access to resources and opportunities, whereas those with initial disadvantages have diminished access to resources and opportunities (cf. Dannefer, 2003). As such, this perspective suggests that initial (social) inequality does not just persist but may actually continue to accumulate through work, resulting in increased social inequality and stratification over time (cf. Martell et al., 1996). However, whereas there is ample research in sociology (DiPrete & Eirich, 2006), economy (Piketty, 2014), and medicine (Warner & Brown, 2011) indicating that people with initial advantages tend to be richer and in better health as they age than those with initial disadvantages, little is known about the role that the workplace plays in these cumulative processes.

Our first aim therefore is to inventorize theoretical support for whether and, if so, how social inequality in workplaces is likely to exacerbate (i.e., the cumulative advantage

perspective). Our inventory indicates that nine mechanisms play a role in how initial differences in opportunities and rewards in workplaces between members of different social groups (e.g., women vs. men, natives vs. migrants, higher vs. lower educated) shape subsequent differences in opportunities and rewards. Two of these mechanisms take place at the individual level (the knowledge, skills, and abilities [KSAs] and the *motivation* mechanisms), one takes place at the dyadic level (the *stereotypes and status beliefs* mechanism), three at the network level (the *homophily*, the *reciprocity*, and the *capital correlations* mechanisms), and three at the organizational level (the *segmentation*, the *winner-take-all structures*, and the *meritocratic ideology* mechanisms). Each of these mechanisms suggests that social inequality in workplace settings can increase over time, thus lending credence to the cumulative advantage perspective.

Further, we aim to explore how these mechanisms interact and influence each other over time. Existing work has studied most mechanisms in isolation from each other and without reference to how they operate over time. While this focus has been helpful to understand how each mechanism might influence inequality in the workplace by approaching them independent from other mechanisms, important complementary insights for—and occasionally critiques of—other domains are lacking. We thus contend that bringing them together can provide important new insights. Although six mechanisms take place at the network or organizational level and are thus theoretically bordering the scope of Organizational Psychology, we argue that attempts to bring together different theories and mechanisms on the (lack of a) meritocratic nature of workplaces should come from Organizational Psychology, given that they all revolve around the relationships between individual performance and opportunities and rewards. Furthermore, Organizational Psychology studies individual experiences and behaviors in the social contexts of organizations. We believe that this inherent

multilevel perspective renders Organizational Psychology especially suitable for studying the aforementioned phenomena. As a consequence, our second aim is to provide a first step toward integrating the different mechanisms by showing how they, in combination, explain how initial differences in opportunities and rewards relate to performance (evaluations), and how such performance (evaluations) shapes subsequent opportunities and rewards.

In doing so, we advance the cumulative social inequality in workplaces (CSI-W) model, which unveils three ways in which workplaces contribute to the accumulation of social inequality. First, the CSI-W shows that each mechanism relates to the others, suggesting that employees who received rewards and opportunities based on merit over time also benefit from non-merit-based advantages, thereby exacerbating social inequalities. Second, the CSI-W indicates that non-merit-based advantages over time can lead to actual improvements in KSAs and corresponding merit-based performance. As such, our integration of mechanisms suggests that, over time, the workplace can legitimate social inequalities. Third, by illuminating the various ways in which opportunities and rewards shape subsequent opportunities and rewards, the CSI-W suggests that the accumulation of social inequality in workplaces is likely to occur incrementally via everyday occurrences and behaviors that, due to their small and incremental nature, are hardly ever captured in empirical research.

Our article provides four main contributions. First, we respond to calls to advance insights into the meritocratic nature of workplaces (Castilla & Benard, 2010; Neckerman & Torche, 2007) and in how processes and mechanisms in organizations contribute to social inequality (Cobb, 2016; Pitesa & Pillutla, 2019; Tsui et al., 2018) by identifying the mechanisms in organizations that together create cumulative social inequality. Second, by providing an initial integration of the different mechanisms, we show how

meritocratic mechanisms tend to feed non-meritocratic social inequality, and how non-meritocratic social inequality is legitimated over time. Third, our overview of these mechanisms sets an agenda on the study of workplace-related causes of social inequality. We especially emphasize the importance of research capturing incremental occurrences and behaviors over time, for example, by adopting age-based approaches capturing employment histories of individuals and sequence-analytic methods for analyzing them. Finally, we offer a number of suggestions for creating a more equal workplace by outlining what measures need to be taken to address and—where needed—to offset non-meritocratic mechanisms to reduce (the accumulation of) social inequality.

The workplace as a conduit for social inequality

When Young coined the term meritocracy in his book *The rise of the meritocracy* in 1958, he used it as a pejorative to warn against an ideology that justifies and legitimizes class differences by suggesting that those class differences have their origins in merit or talent (Young, 2001). The satirical meaning of the term was however lost, and it is now associated with a social system where contribution or utility forms the basis for distributing opportunities and rewards (Castilla & Benard, 2010). The human capital earnings function (Becker, 1964; Mincer, 1974) theoretically justifies such an allocation by asserting that opportunities and rewards are the result of job performance that, in turn, is a function of an individual's capabilities. Most modern capitalist organizations and societies ascribe to this ideal by having a tightly coupled performance appraisal and reward system (Castilla, 2008; Schraeder & Jordan, 2011). Such performance-based rewards systems suggest that everyone has an equal chance to receive opportunities and rewards regardless of their socioeconomic background. Even though individuals

belonging to historically disadvantaged groups tend to grow up with fewer resources and opportunities, this meritocratic perspective suggests that workplaces provide an environment where only an individual's capabilities matter and where, over time, individuals can overcome initial disadvantages.

An important assumption underlying this meritocratic perspective is that one's capabilities mainly stem from their innate qualities (e.g., personality and general intelligence). Consider two persons of the same age who have the same innate capabilities. The first is a White man named Jason who grew up in a rich family and neighborhood and was able to attend a prestigious private university. The second is a Black woman named Jess who grew up in a poor family and neighborhood and could only attend a community college. Due to his prestigious education, Jason starts at an advantaged position in the labor market and may land a job in a higher position than Jess. The meritocratic perspective on workplaces suggests that despite this initial advantage of Jason, Jess over time will arrive at the same level as Jason if she is able to prove her worth. That is, because she started at a lower ranking job, she might be better able to outperform her colleagues and distinguish herself compared to Jason. A meritocratic organization is thus considered to recognize the surplus in Jess' capabilities and provide her with the environment and opportunities that enable her to quickly rise to Jason's level (cf. van Dijk et al., 2019).

As such, the meritocratic perspective suggests that an individual's capabilities drive performance and determine the opportunities and rewards that one accumulates over time. Although this *does* entail that inequalities over time accumulate in workplaces, such cumulative inequalities are considered to be based on *individual* differences in capabilities and not based on social group membership. In fact, assuming that capabilities are equally distributed across social groups, the meritocratic perspective suggests that over time, workplaces

will contribute to social *equality* by providing opportunities and rewards based on capabilities and corresponding performance levels regardless of initial social inequalities. The exception here is social inequality between those with higher versus lower educational qualifications, given that educational qualifications are supposed to reflect differences in capabilities, and increasing inequalities between those groups thus are considered to be merit-based.

However, decades of research on diversity and inequality in organizations have challenged this assumption of workplaces as conduits for social equality (Tolbert & Castilla, 2017; Zanoni et al., 2010). Social group membership is rarely—if ever—a good proxy for merit, yet ample research shows that social group membership frequently relates to the distribution of opportunities and rewards. For example, women tend to earn less than men for doing the same job (Arulampalam et al., 2007; Rubery & Grimshaw, 2015) and members of minority ethnic groups tend to be promoted less often than members of the dominant ethnic group who hold similar credentials (Carton & Rosette, 2011; Heath et al., 2008; Parks-Yancy, 2006). It is safe to say that the diversity literature has shown that individuals belonging to historically disadvantaged groups face a number of obstacles and challenges in workplaces that inhibit their performance and/or cause lower performance evaluations, which reduce the opportunities they have access to and the rewards they receive (Acker, 2006; van Dijk et al., 2017; Zanoni et al., 2010).

A caveat of much of this research on diversity and social inequality in workplaces is that it adopts a static approach by examining how social group membership relates to social inequality at a fixed point in time (e.g., recruitment, promotion, and parenthood). As a consequence, those studies indicate that inequality exists and persists in workplaces, but there is little insight in whether and, if so, how such (initial) social inequality over time shapes *subsequent* social inequality. Insights into cumulative dynamics are crucial for

understanding the full range of potential workplace-related causes and remedies of social inequality and for assessing the real extent to which workplaces actually contribute to social inequality.

Consider a study that aims to assess if promotion procedures are biased against women in a company where men are overrepresented in the top management team (TMT). A static approach is likely to focus only at promotion into the TMT. If it identifies a 1% bias against women, that bias is likely to be dismissed as nonsignificant, suggesting that men's overrepresentation in the TMT is based on different life and career choices between men and women or even that men provide more merit. However, this bias is much higher if its accumulation throughout the organization's hierarchy is taken into account. For example, if there are eight hierarchical levels in the organization, then a "nonsignificant" bias of 1% at each level becomes rather substantial after eight iterations, such that women represent just 35% of the TMT positions in the organization due to the accumulation of gender bias (Martell et al., 1996). Such a cumulative dynamics approach thus suggests that some social inequalities that may be dismissed as nonsignificant when considered only once and at a fixed point in time may in fact represent a large effect when its incremental accumulation is considered over time.

Whereas there are hardly any studies in Organizational Psychology that have taken a cumulative dynamics approach, such studies are more common in other domains. Research on cumulative advantage in relation to inequality typically examines whether interindividual inequality grows over time (Dannefer, 2003; DiPrete & Eirich, 2006). In organizational contexts, this research has shown that income inequality among individuals tends to increase with age (Crystal & Waehrer, 1996; Dannefer & Sell, 1988; Disney & Whitehouse, 2002; O'Rand, 1995; O'Rand & Henretta, 1999), and studies focusing on employment have provided evidence

of patterns of cumulative career advantage (Heath et al., 2008). However, most research on cumulative advantage has focused primarily on exploring which advantages and disadvantages have cumulative effects. This has resulted in a proliferation of terms to describe cumulative advantage-related phenomena in a variety of contexts, for example, research on the first-mover advantage in strategy (e.g., Kerin et al., 1992), increasing returns in economy (e.g., Pierson, 2000), halo effects in psychology (e.g., Cooper, 1981), path dependency in organizations (e.g., Sydow et al., 2009), and general descriptions in various literatures of virtuous and vicious cycles, success breeding success, and “the rich getting richer and the poor getting poorer.” Surprisingly, fewer studies have examined the mechanisms underlying such cumulative advantage phenomena. This is nevertheless necessary for identifying the causes of cumulative advantage and, in turn, understanding what can be done about it. To address this need, in the following section, we present our inventory of different mechanisms on cumulative advantage.

The CSI-W model

Given that an understanding of an organizational phenomenon requires insights from various perspectives (Schwarz & Stensaker, 2014; Sparrowe & Mayer, 2011), we identified workplace-related cumulative social inequality mechanisms by searching for theories on cumulative phenomena in various literatures, ranging from developmental psychology and gerontology to sociology and economics. We selected mechanisms that (a) provided a clear explanation of how initial opportunities and rewards affect subsequent opportunities and rewards via performance (evaluations), (b) could account for the accumulation of *social* inequality, and (c) have been examined in organizational settings, or are likely to operate in a similar way in the workplace. Because our focus is on what happens in the workplace, we did not select mechanisms operating purely at

the societal level (e.g., pertaining to national culture or legislation). A difficulty in identifying mechanisms was that some theories on such mechanisms are rather implicit, do not explicitly focus on social inequality, and/or do not focus on workplaces. Therefore, several mechanisms that we selected are not explicitly discussed in the literature as mechanisms on how initial social group-based advantages in workplaces shape subsequent advantages, but we deduced such mechanics from the original theories and studies (e.g., the KSAs mechanism). We merged mechanisms when the proposed underlying process was similar, for example, mechanisms based on stereotypes (e.g., van Dijk et al., 2017) and mechanisms based on status beliefs (e.g., Magee & Galinsky, 2008). Our final selection consisted of nine mechanisms.

To facilitate an understanding of similarities and differences among mechanisms, we adopted a multilevel perspective and categorized each mechanism into one of the four levels: the individual, dyadic, network, or organizational level. This categorization is mainly based on the level at which the predominant theory and research regarding a specific mechanism focuses, but it does not imply that there are no cross-level effects. For example, whereas diversity research in Organizational Psychology tends to build on Byrne’s (1971) attraction paradigm to explain why people prefer similar others (thus placing preference for similar others at the dyadic level; e.g., Williams & O’Reilly, 1998), in Sociology there is a longer standing history of research on homophily that makes a similar point regarding social groups and networks (cf. Lazarsfeld & Merton, 1954). Given that it is older and—in our eyes—provides a more thorough explanation of how a preference for similar others in workplaces affects cumulative social inequality, for this specific mechanism we follow the sociological tradition and have placed the mechanism at the network level. We thus posit that mechanisms in general operate at their specific level and that mechanisms at a similar level operate based on similar principles that differ from mechanisms at

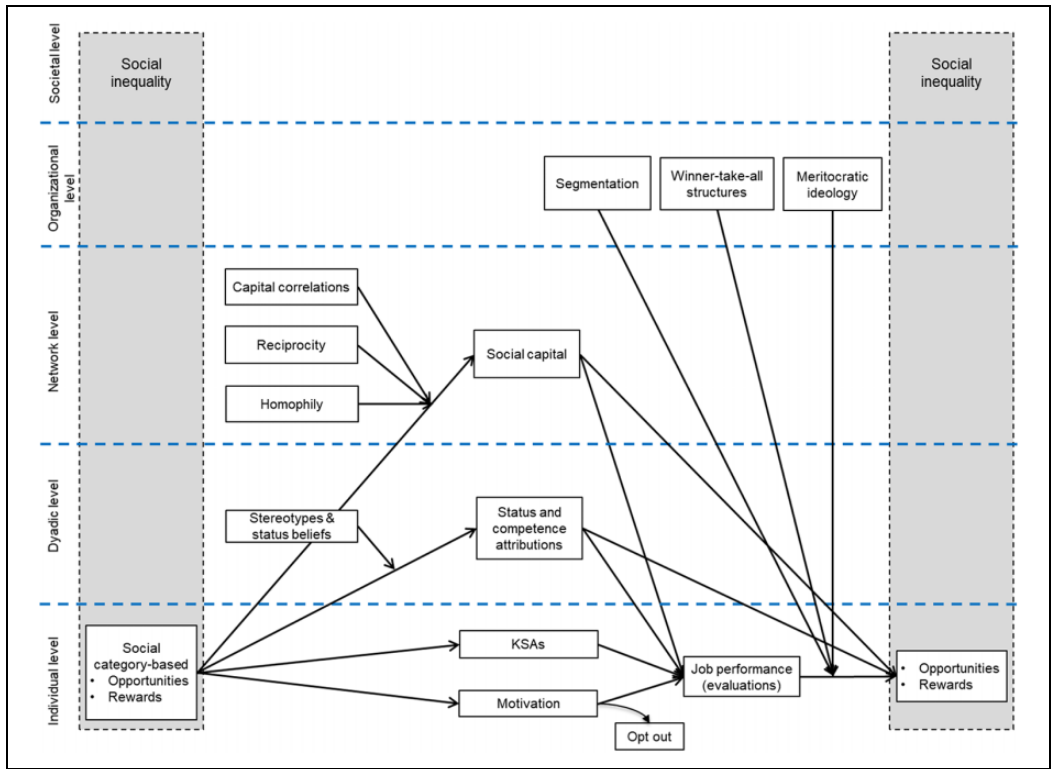

Figure 1. The CSI-W model. CSI-W = cumulative social inequality in workplaces; KSAs = knowledge, skills, and abilities.

other levels. However, mechanisms may also manifest at other levels, if only because the different mechanisms tend to influence each other.

Because our interest is not in merely reviewing the mechanisms but also in showing how they may reinforce or offset each other over time, our next step was to integrate the mechanisms into the CSI-W model (see Figure 1). In this model, we conceptualize social inequality as an emergent construct at the societal level that refers to differences in opportunities and rewards between individuals belonging to different social categories. As such, it reflects differences between, for example, majority and minority members in whether they have a specific high-status job, achieve a desired promotion, have an influential

person as a mentor, are granted access to a training, received a bonus, and so on. Furthermore, whereas research into diversity and social inequality generally looks at social category-based opportunities and rewards as the dependent variable only (Zanoni et al., 2010), our model focuses on what happens next, and specifically how such social category-based opportunities and rewards in workplaces shape subsequent social inequality over time. Our model thus starts and ends with social inequality (cf. van Dijk et al., 2017). Some theories underlying the mechanisms have been used extensively in research into diversity and inequality. However, in showing how they can create cumulative dynamics of social inequality and reinforce or offset the other mechanisms, the application of those theories is novel.

To distinguish between social inequality as a starting point (on the left-hand side of our model, see Figure 1) and social inequality as an end point (on the right-hand side of our model), we refer to social inequality on the left as *initial* social inequality (and initial opportunities and rewards) and to social inequality on the right as *subsequent* social inequality (and subsequent opportunities and rewards). However, subsequent social inequality also serves again as input, meaning that the model represents a dynamic, ongoing process that can consist of various iterations. In other words, the CSI-W model suggests that the mechanisms do not change over time, but that the consequences of the mechanisms become stronger with more iterations. Although it is likely that more linkages exist between the mechanisms, for the sake of parsimony we limited the integration to the main elements that the mechanisms have in common: initial opportunities and rewards, job performance (evaluations), and subsequent opportunities and rewards.

In the following, we first explain how each mechanism suggests that initial opportunities and rewards shape subsequent opportunities and rewards. We start with mechanisms at the individual level and continue upward to discuss mechanisms at the organizational level. Then, we discuss three main insights that emerge from the integration of mechanisms in the CSI-W.

An overview of each mechanism

The individual level

Mechanisms at the individual level suggest that initial opportunities and rewards directly affect the individual employee in their functioning and corresponding performance, which over time influences the employee's subsequent opportunities and rewards. The CSI-W model distinguishes between two mechanisms at the individual level: (1) KSAs and (2) motivation.

The *KSAs mechanism* shares the assumption of the meritocratic perspective that opportunities

and rewards are the result of job performance that, in turn, is a function of an individual's capabilities. However, instead of assuming that capabilities only stem from an individual's *innate* qualities, it posits that capabilities manifest themselves via KSAs that are *learned*. Because various opportunities and rewards (e.g., promotion and receiving training) lead to the further development of KSAs (Tomaskovic-Devey, 1993), those with more initial opportunities and rewards are likely to accumulate more KSAs and, hence, more subsequent opportunities and rewards. Although the KSAs mechanism is in general agnostic regarding (initial) differences in opportunities and rewards between members of different social groups, it does suggest that when individuals from different social groups differ in their opportunities and rewards, such initial social inequalities are likely to accumulate over time. And given that several social groups tend to differ in KSAs due to different opportunities early in their life and/or different ways of socialization (e.g., Whites vs. Blacks, high vs. low socio-economic status), the KSAs mechanism suggests that over time social inequalities will further increase due to differences in the accumulation of KSAs.

Consider the example of Jess and Jason. The KSAs mechanism suggests that Jason in his higher position is challenged more, which helps him to further develop his KSAs. In contrast, Jess experiences few challenges in her position, which also leaves her little room for personal development. Although that may mean that she is more likely to make a promotion in a relatively short amount of time because of her performance, in the meantime Jason may stay ahead of her because he has developed more KSAs and may thus continue to outperform Jess.

Whereas the KSAs mechanism still shares the assumption with the meritocratic perspective that individual performance is based on one's capabilities, the *motivation* mechanism challenges that assumption. The motivation mechanism is grounded in the theory of limited

differences (Cole & Cole, 1973; Cole & Singer, 1991), which posits that inequality is caused by prior experiences of success and failure, called “kicks,” and the individual’s reaction to those kicks. Positive kicks (e.g., getting a desired job or promotion) are supposed to result in motivation to work harder, whereas negative kicks (e.g., not getting that job or promotion) decrease such motivation (see also Heckhausen et al., 2010). This motivation, in turn, is expected to shape the individual’s job performance and subsequent opportunities and rewards. Because being granted [or denied] an opportunity or reward constitutes a kick that according to the theory of limited differences enhances [or inhibits] an individual’s motivation, over time the accumulation of such kick-reaction sequences leads to a “multiplier effect” (Cole & Singer, 1991, p. 283): increasing differences in job performance and associated opportunities and rewards between those experiencing positive kicks versus those experiencing negative kicks.

Members of historically disadvantaged groups can be expected to be less motivated because they have experienced more negative kicks and have less initial opportunities and rewards. According to the motivation mechanism, such lower levels of motivation negatively affect performance, subsequent opportunities and rewards, and ensuing motivation levels. In the example of Jess and Jason, the motivation mechanism means that the challenging position motivates Jason to put in extra effort, whereas the less-challenging position demotivates Jess and may cause her to perform below her potential (cf. Crosby, 1976; Erdogan & Bauer, 2009).

Repeated demotivational experiences may even cause historically disadvantaged group members to opt out of pursuing ambitious goals. Such consequences of demotivational experiences are illustrated by a recent study showing that African American and Hispanic American entrepreneurs tend to be more discouraged toward important opportunities and entrepreneurial tasks because of negative sociohistorical experiences compared to White American

entrepreneurs (Neville et al., 2018). In a similar vein, women have been argued to drop out of the leadership pipeline because experiences of stereotype threat demotivate them to pursue leadership positions (Hoyt & Murphy, 2016). Based on the assumption that social category membership relates to the level of initial opportunities and rewards that individuals receive, the motivation mechanism thus suggests that initial social inequalities in workplaces will accumulate over time.

The dyadic level

The *stereotypes and status beliefs* mechanism at the dyadic level is grounded in the assumption that differences in performance, opportunities, and rewards between individuals originate from evaluators’ assessments of and responses to a target individual’s competence and associated status (i.e., attributed respect, prominence, esteem, and influence; Anderson et al., 2001). Expectation states theory (Berger et al., 1974), status hierarchies theory (Gould, 2002), and the Pygmalion effect (Rosenthal & Jacobson, 1968) all assert that higher competence and status perceptions lead to increased attention and support from perceivers (e.g., colleagues and supervisors), because (contributions of) individuals who are attributed higher competence and status levels are expected to be of more merit than (contributions of) individuals with lower attributed competence or status (Rucker et al., 2018; Wittenbaum & Bowman, 2005). In turn, higher levels of attention and support are likely to result in more opportunities and rewards directly (e.g., in the form of mentorship; Kierein & Gold, 2000) or indirectly by facilitating performance and/or yielding more positive performance evaluations (van Dijk et al., 2017). Merton’s (1968) description of the Matthew effect outlines how such opportunities and rewards reinforce the same mechanism at the individual level: targets who have received an opportunity or a reward are considered to be more competent and are attributed higher status

than those who have not been granted an opportunity or reward. Because of their attributed competence and status, they receive more credit and recognition for subsequent work, which further improves competence and status attributions (cf. Magee & Galinsky, 2008).

Merton (1968) argued that such cumulative inequalities between individuals find their origin in different innate capabilities, thus suggesting that the causes of these differences in opportunities and rewards are meritocratic and, hence, legitimate. However, regarding differences in opportunities and rewards between members from different social groups, research on stereotypes and status beliefs suggests otherwise. Various theories about stereotyping (e.g., stereotype content model, Fiske et al., 2002; role congruity theory, Eagly & Karau, 2002; lack-of-fit model, Heilman, 1983) and status (e.g., status characteristics theory, Berger et al., 1972; status construction theory, Ridgeway, 1991) indicate that competence attributions are influenced by stereotypes and status beliefs of social groups. The result is that those who are subject to negative [positive] competence stereotypes and status beliefs tend to be undermined [supported] in a variety of ways, causing them to perform worse [better] and causing others to evaluate their performance as worse [better], which decreases [increases] their opportunities and rewards and, in turn, confirms and reinforces status and competence attributions (cf. Cuddy et al., 2007; Rudman & Fairchild, 2004; van Dijk et al., 2017; van Dijk & van Engen, 2019). Because such stereotypes and status beliefs are omnipresent in workplaces (Magee & Galinsky, 2008), the stereotypes and status beliefs mechanism thus suggests that initial social inequalities will accumulate over time through work.

In the example of Jess and Jason, the relatively young age of Jason in his position in combination with his background makes it more likely that he will be considered a “talent,” which tends to come with more support, mentorship, training, and possibly higher

performance evaluations. Jess, in contrast, is more likely to be seen as being in a position that fits a Black woman who graduated from a community college, which may also result in relatively lower performance evaluations.

The network level

Mechanisms at the network level suggest that differences in job performance and in opportunities and rewards between individuals belonging to different social groups originate from differences in social capital, which refers to resources embedded in a person’s social network that can be accessed and/or mobilized (Lin, 2002; see also DiMaggio & Garip, 2012). Social capital is known to affect the individual’s performance and opportunities and rewards in a number of ways (cf., Burt, 2005; Seibert et al., 2001). First, social resources theory (Lin et al., 1981) suggests that social capital supplements a lack in an individual’s KSAs and can thereby boost the individual’s performance, for example, when another person in an individual’s network lends a helping hand. Second, from a social learning perspective (Borgatti & Cross, 2003), an individual’s social capital is expected to represent an important source for learning knowledge and skills that can enhance performance (Dolfsma & van der Eijk, 2016). Third, structural holes theory (Burt, 2000) suggests that social capital determines the extent of access to colleagues and networks outside one’s own network or sphere of influence, which can enhance personal opportunities.

We identified three complementary mechanisms that explain how social inequality is likely to develop through work at the network level. First, individuals who differ in their social category membership are expected to differ in their social capital due to *homophily*, which is defined as the tendency of individuals to form connections with and share the opinions and behaviors of others who are similar in terms of demographics, history, status, values, or other attributes (Byrne, 1971; Kilduff & Brass, 2010;

Lazarsfeld & Merton, 1954; McPherson et al., 2001). Individuals and groups seek similar others because a high degree of similarity offers advantages in interactions, such as facilitating communication and sharing of tacit knowledge, enhancing feelings of predictability and trust, as well as easing coordination and reducing the possibility of conflicts (Bacharach et al., 2005; Borgatti & Foster, 2003; DiTomaso et al., 2007; Ibarra, 1995; Schneider, 1987). An implication of this general tendency of “birds of a feather to flock together” is that there tend to be differences between social groups in their social capital, such that, for example, majority group members tend to be part of networks with other majority group members, causing such networks to be more homogeneous and richer in social capital compared to networks consisting of minority group members (cf. Ibarra, 1992, 1993, 1995; McPherson et al., 2001). In turn, these social capital benefits of majority group members translate into higher job performance and opportunities and rewards for majority group members, creating a further accumulation of social capital in the networks of majority group members compared to those of minority group members. Following this reasoning, Jason is more likely to be adopted by an informal social network of White men and/or alumni from his university, who tend to be disproportionately present among the upper echelons. In contrast, Jess is more likely to become part of a social network of Black women in the organization, who present-day are more likely to represent the lower organizational ranks.

The second mechanism at the network level, *reciprocity*, is grounded in research on the norm of reciprocity, which is defined as the expectation and corresponding tendency of people to reciprocate a favor (Gouldner, 1960). One of the reasons why people invest in building and maintaining networks is because they lead to individual and collective benefits (Adler & Kwon, 2002). Ideally, all members of a network participate as donors and recipients to a similar extent, generating a mutual exchange of resources and

information and, as a consequence, optimal returns on investment for all members involved (Portes, 1998; Thibaut & Kelley, 1959). If not all members are able to give and take to the same extent, the norm of reciprocity can lead to the exclusion of those members who contribute less to the network than they take (Kanter, 1977; Portes, 1998). The reciprocity mechanism thus suggests that networks that are initially diverse may become more homogeneous over time, because members from historically disadvantaged groups are less likely to be able to contribute equally compared to members from advantaged groups. Furthermore, because members of different social networks are likely to differ in the opportunities and rewards that they receive, over time the ability of members to reciprocate becomes more disparate. The reciprocity mechanism thus suggests that social inequality over time increases through work because social networks become less diverse and because the ability of members among different social networks to reciprocate becomes more disparate. As a consequence, whereas Jess and Jason may initially be part of the same network of new employees, its members may gravitate more toward Jason because he has more power and resources in his position. In using that power and resources to help others, they may reciprocate the favor, thereby granting more help and support to Jason. Since Jess is less likely to reciprocate favors of network members due to her lower ranked position in the organization, over time Jason and his equally reciprocating network partners may create a subnetwork that Jess is excluded from.

The third mechanism at the network level is *capital correlations*. According to social reproduction theory (Bourdieu, 1996), there are several forms of capital that affect each other and exacerbate societal stratification. Specifically, a distinction is made between social capital, economic capital (i.e., capital that is convertible to money; Bourdieu, 1986), and cultural capital (i.e., proficiency in and familiarity with dominant cultural codes and practices; Aschaffenburg & Maas, 1997, p. 573; cf. Stephens et al., 2014).

Social reproduction theory suggests that getting access to one form of capital tends to give one access to other forms of capital. For example, economic capital enables an individual to go to a better school, which increases the individual's cultural and social capital. These links among economic, cultural, and social capital tend to further contribute to a homogenization and stratification of social networks among individuals who differ in their social category membership. Specifically, although opportunities and rewards frequently come in the form of economic capital (e.g., bonuses, invitations to events), social reproduction theory suggests that such economic capital can partly—if not wholly—contribute to or be exchanged for social capital. For example, a promotion can result in access to individuals who are higher in the organizational hierarchy, whereas bonuses or salary increases can be used to obtain access to professional networks. The capital correlations mechanism thus suggests that (initial) opportunities and rewards can be used to increase one's social capital, thereby increasing differences between social groups in their social capital and subsequent opportunities and rewards. This mechanism suggests that Jason already makes a head start compared to Jess, not just because of starting in a higher position, but because his background has provided him with richer cultural capital, and because the higher position comes with connections to higher ranked others with more social capital.

The organizational level

Mechanisms at the organizational level affect how (the evaluation of) performance translates into opportunities and rewards. As an example, consider a CEO who performs 5% better than her peers. It is generally accepted in Western organizations that such CEOs can also receive a 5% salary increase—at least. However, such practices are much less likely to be applied to, for example, social workers who outperform their peers by a 5% margin. The following three mechanisms provide different rationales for

how organizational-level practices determine how performance (evaluations) translates into opportunities and rewards.

The *segmentation* mechanism covers two types of segmentation that explain in different ways how organizational practices create differences in opportunities and rewards between social groups: organizational segmentation and occupational segmentation (cf. Baron & Bielby, 1980; Kalleberg, 2003; Kalleberg et al., 1981). Organizational segmentation is based on dual economy theory, which distinguishes between two different types of sectors and corresponding organizations. The “core” sector consists of large, oligopolistic firms with a great deal of control over their product markets. These organizations can offer their employees high earnings, bonuses, stable employment, and attractive nonmonetary benefits. Moreover, because of their size, they can offer employees attractive career opportunities. The “periphery” sector, in contrast, consists mostly of small, single, or few product firms with few resources and little control over their product markets. Employees in such organizations are more likely to find themselves in precarious employment with low earnings, little job security, and few chances on promotion (Kalleberg et al., 1981). Occupational segmentation refers to a similar distinction between core and peripheral occupations, which is based on power differences among occupational groups established through collective, institutionalized arrangements between employers and workers (e.g., unions). Employees in occupations that are unionized and require scarce skills tend to have more power over their employers. As a consequence, such core occupations (e.g., accountancy) tend to offer permanent employment relationships and provide more access to resources (e.g., benefits, opportunities for promotion) than the peripheral occupations (e.g., work in a restaurant) that tend to offer more nonstandard employment relationships (e.g., temporal, part-time, or contract work) and provide less access to resources (Hartmann, 1976; Kalleberg, 2003; Lambert, 2008).

The segmentation mechanism suggests that these differences between core and peripheral organizations and occupations accumulate social inequality through work in two ways. First, social group membership is known to affect an individual's access to organizations and occupations, such that core organizations and occupations are more likely to be dominated by members of advantaged groups (Acker, 2006; Baron & Pfeffer, 1994). This entails that the performance of advantaged members tends to yield more and better opportunities and rewards in comparison with the performance of members of disadvantaged groups. Second, individuals who perform less well and receive fewer opportunities and rewards (i.e., at the individual level) are more likely to move to organizations and occupations in the periphery. Because other mechanisms suggest that the performance of disadvantaged group members is likely to be lower than that of advantaged group members, the proportion of disadvantaged group members in core organizations and occupations is likely to decrease over time (cf. Martell et al., 1996). This mechanism thus suggests that, compared to Jess, Jason is more likely to find employment in a core occupation with higher levels of power and better working conditions, including a higher increase in pay for better performance than Jess.

The second mechanism at the organizational level, *winner-take-all structures*, is grounded in research on the model of superstars (Rosen, 1981), the model of winner-take-all markets (Frank & Cook, 1995), and the tournament mobility model (Rosenbaum, 1978, 1984). These models propose that opportunities and rewards are disproportionately granted to the highest performers in an organization and those with the strongest talents. There are three explanations for this unequal distribution. First, there is an imperfect substitution among different performers: since lower performance or weaker talent is a poor substitute for higher performance or greater talent, demand for the

better performers or talents increases more than proportionately. As Rosen (1981, p. 846) puts it: "If a surgeon is 10 percent more successful in saving lives than his fellows, most people would be willing to pay more than a 10 percent premium for his services." In line with this reasoning, many organizations adopt an exclusive approach to talent management by providing a limited pool of employees with more resources, thus assuming that some people are inherently more talented (Dries, 2013). Second, the allocation of resources (e.g., rewards and opportunities) tends to be based on the existence of relatively stable, institutionalized social entities that contain a relatively fixed number of positions to which individuals are allocated. For example, organizations provide incentives to their employees by promoting their best performers to higher paying jobs. This creates a "tournament" or competition among employees to win the higher salary and the option to continue competing for even higher level jobs. Since only one or a few employees will "win" and move up in the hierarchy, employees who enter in the same cohort become increasingly differentiated with the passage of time as some remain in the "main game" while others are sidelined to a "minor tournament" with a restricted range of (lower status) positions to move into and a lessened probability of making a move (Rosenbaum, 1984; see also Kanter, 1977). Third, progressively fewer positions are available higher up in the hierarchy, thus reducing the chances of winning the tournament. To motivate employees to take part in the tournament, the reward differences between the lower and higher level jobs at the top of the hierarchy are usually larger, which further increases inequality across the hierarchical layers of organizations.

Taken together, these reasons suggest that winner-take-all structures cause top performers to receive disproportionately more opportunities and rewards. Given that the other mechanisms suggest that members of historically advantaged groups are more likely to be among the top performers compared to members of historically

disadvantaged groups, winner-take-all structures tend to contribute to the accumulation of social inequality through work over time. For example, if Jess did manage to get a promotion before Jason did, then for a next promotion she is likely to have to compete with Jason. Given Jason's surplus in experience in their current position, he is likely to perform better at such a point and thus get the promotion. Meanwhile, she'll have to wait until another higher position becomes available.

Finally, the third mechanism at the organizational level is *meritocratic ideology*, which captures the extent to which organizations endorse the principle that opportunities and rewards ought to be distributed on the basis of performance. Paradoxically, emphasizing a merit-based distribution of rewards and opportunities tends to evoke more biased distributions, such that historically advantaged group members receive more opportunities and rewards than equally qualified and well-performing historically disadvantaged group members (Castilla & Benard, 2010). Whereas there is some uncertainty around the exact reasons for such biased distributions, the state of the research suggests that they are caused by making people blind to their own biases (Monin & Miller, 2001). That is, a meritocratic ideology tends to cause people to explain group differences based on differences in merit and to resist initiatives aimed at enhancing equality (Major & Kaiser, 2017). A meritocratic ideology thus makes members less suspicious about causes other than merit that drive performance differences (Haack & Sieweke, 2018; Jost & Hunyady, 2005) and gives evaluators the impression that their judgments are fair and balanced and in no need of correction (Castilla & Benard, 2010; Major & Kaiser, 2017; cf. Castilla, 2008), which increases the likelihood that the performance of historically advantaged members is rewarded more positively than the performance of historically disadvantaged members. As such, a meritocratic ideology tends to increase the likelihood that opportunities and rewards are distributed

unevenly across members of different social groups, causing social inequality to accumulate through work over time. In the example of Jess and Jason where they are both competing for the same promotion, even if their performance is on par, selection committees may still grant the position to Jason because they consider his experience and educational background as indicators of having more potential and are blind to hurdles that Jess overcame to get where she is.

Overall model dynamics

In combination, the nine mechanisms outline the dynamics of how initial social inequality shapes subsequent social inequality through work, such that social inequalities accumulate over time. Furthermore, by providing an initial integration of the mechanisms, the CSI-W shows that the consequences of each mechanism provide input for the other mechanisms. Each mechanism thus does not just reinforce itself but also provides an impetus for the other mechanisms. To explain and elaborate on how such relationships among the different mechanisms shape system dynamics, in the following we delineate three overall implications that can be drawn from the CSI-W model regarding the dynamics of social inequality in workplaces.

The exacerbation of social inequalities

A first implication of the interactions among mechanisms is that they tend to exacerbate the impact of individual mechanisms on the accumulation of social inequality over time. Specifically, in suggesting that all mechanisms feed into each other, the CSI-W indicates that employees who received opportunities and rewards based on merit (i.e., individual capabilities and input) also benefit from non-merit-based advantages. Being rewarded for one's performance doesn't just help one to further accumulate KSAs, it is also motivating, brings more status, and provides access to more social capital. In contrast, those who just fall behind in

performance and are given fewer rewards may not get access to a training that would help them to further improve their KSAs, become more demotivated, gain less status, and are not granted access to specific social networks that could enhance their social capital.

In particular, when there are winner-take-all structures in place, such non-merit-based advantages and mechanisms may determine who receive rewards and opportunities and who do not. When Jason is promoted over Jess, the resulting motivation boost makes it likely that Jason will put in more effort to succeed in his new position. In his new position, he will be introduced to new, higher ranked colleagues that grant him access to a new social network with more social capital. Furthermore, in being promoted and being associated with more prominent organizational members, he will be bestowed more status and considered more competent. All these elements will help him to succeed in the new job and differentiate himself more from Jess, who—if anything—is likely to be demotivated by being rejected the promotion and cannot enjoy all the other benefits.

By considering all mechanisms in concert, the CSI-W thus shows how initial differences in KSAs (and associated opportunities and rewards) over time can be exacerbated through work—even in the case of equal innate capabilities. Opportunities and rewards do not just help to accumulate more KSAs, but they also yield a number of other non-meritocratic benefits that create increasing disparities. And because the different mechanisms suggest that opportunities and rewards for various reasons are less likely to be granted to members of historically disadvantaged groups, the CSI-W suggests that social inequalities over time do not just persist but actually accumulate through work.

The legitimization of social inequalities

Second, the CSI-W shows how workplaces can legitimize social inequalities over time. The

clearest way in which this happens is that all mechanisms directly or indirectly translate into performance differences. Because such performance differences are often attributed to individual's qualities—in particular in workplaces with strong meritocratic ideologies, each mechanism contributes to the perception that corresponding differences in opportunities and rewards between members from different social groups are legitimate.

Another, more intricate way in which such a legitimization of social inequality occurs is that each mechanism over time can affect the accumulation of KSAs. In the case of Jess and Jason, even if they would have started at a similar position in a core company, then still Jason is more likely to fit in better and gain access to more social capital because of his background (cf. Gray & Kish-Gephart, 2013; Stephens et al., 2014). As a consequence, Jason may receive better mentoring, coaching, and feedback, which will improve his KSAs over time. In contrast, Jess may struggle more to find her place, make fewer and only lower quality connections to more senior people, and therefore be relatively deprived of opportunities to improve KSAs. In staying behind in KSA development, Jess is less likely to make a promotion and, over time, more likely to drop out and move to a peripheral company, where she has even less chances of developing her KSAs (cf. Ossenkop et al., 2015).

Thus, in shaping the development of KSAs over time, even non-meritocratic mechanisms can create the impression that performance differences between members from different social groups reflect differences in KSAs. The connections between the different mechanisms can therefore make it very difficult to disentangle meritocratic from non-meritocratic contributions. And because evaluators tend to attribute individual performance more to personal qualities over external conditions (Groysberg, 2010), the CSI-W suggests that work legitimizes and justifies social inequalities over time.

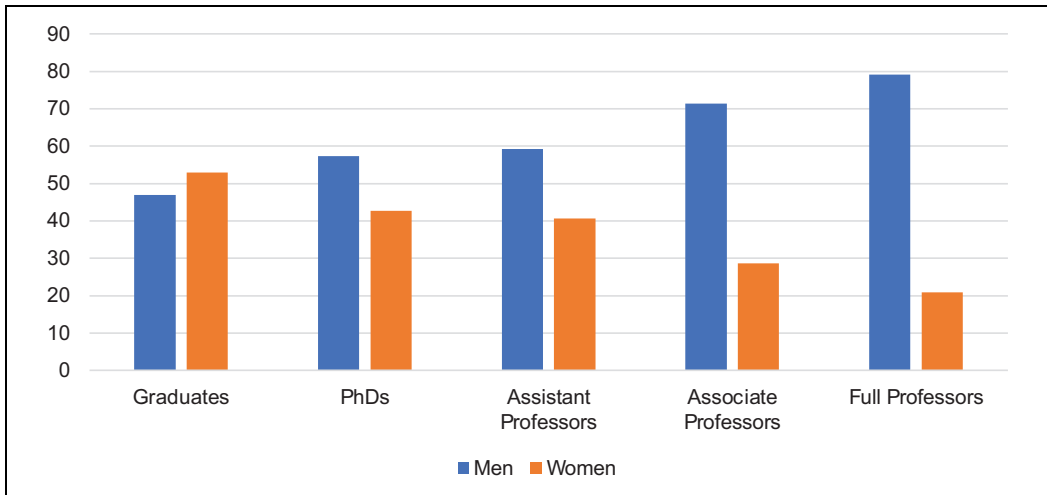

Figure 2. Representation of men and women at all Dutch Universities on October 1, 2017, in persons, excluding the domain of Health (Landelijk Netwerk Vrouwelijke Hoogleraren, 2018, p. 12).

Social inequalities accumulate through everyday occurrences and behaviors

Whereas the first two implications focus on how social inequalities accumulate and become accepted, respectively, this third implication focuses more on the nature of the different mechanisms. Research on diversity and social inequality tends to focus on the major transitions (e.g., recruitment and selection, promotion, and becoming a parent) and prominent positions (e.g., leadership and TMTs), which is where inequalities between social groups tend to be most visible. Consider the distribution of men and women across the different ranks at all Dutch universities (see Figure 2). The difference between men and women is most evident at the full professor level, which makes it understandable that attention tends to drift toward such highly salient instances of social inequality in workplaces.

However, the CSI-W suggests that such highly visible instances of social inequality are likely to result from repeated iterations of social inequality dynamics at earlier stages. As such, the disproportional representation of men among the highest rank may represent little

more than a symptom of the actual problems in lower ranks. Efforts focusing on improving the representation of women in the highest rank (as is common in many organizations and governmental policies by focusing on the representation of women in upper echelons) may therefore fail to address the actual, underlying causes of such social inequalities. Instead, the CSI-W suggests that the actual problems start at the level before the one where differences between social groups become visible. In relation to the university example, this means that attention should go to what happens at the graduate level, given that differences between the proportion of men and women become visible at the PhD rank. The disproportionate promotion of men to PhD and subsequent positions compared to women then represents manifestations of the more subtle, latent causes of cumulative social inequality.

Pinning down such latent causes is hard, given that social inequality dynamics outlined in the CSI-W indicate that social inequality accumulates incrementally. With the exception of the segmentation and the winner-take-all mechanisms that do focus on more visible and

salient disparities between members from different social groups, the mechanisms in concert suggest that such social inequality increments can consist of a simple invitation to join a meeting, being recognized for one's contributions to a successful project that increases one's status, or being motivated by a sign of approval from colleagues. Such everyday occurrences and behaviors may be difficult to capture and, as mentioned before, easily dismissed as non-significant or irrelevant when considered in isolation, but based on the CSI-W, we argue that they are crucial to the emergence and accumulation of social inequalities through work.

Discussion

The recent surge in the number of publications on how organizations tend to contribute to inequality (e.g., Cobb, 2016; Pitesa & Pillutla, 2019; Stephens et al., 2014; Tolbert & Castilla, 2017; Tsui et al., 2018) follows decades of research on diversity, which has attempted to explain the ways in which individuals, on the basis of their social group membership, have been disadvantaged in organizations (Acker, 2006; Zanoni et al., 2010). We contribute to the more recent literature on inequality as well as the more established literature on diversity in organizations by providing an understanding of the mechanisms via which social inequalities accumulate over time, which we argue is crucial for a more thorough understanding of the causes and consequences of social inequalities in the workplace.

Our first step toward an integration of distinct mechanisms situated at four different levels in the CSI-W model strongly suggests that workplaces play a profound role in the reproduction of social inequality, causing social inequality to become more pronounced over the life span. This focus on the dynamics of social inequality over time is crucial as it indicates that even small and apparently unimportant differences between social groups can, over time, create substantial

social inequalities. The CSI-W suggests that social inequality mainly accumulates and exacerbates through everyday occurrences and behaviors that are often not captured in the more static and positivistic research designs that tend to predominate the field.

By pointing out that social inequalities tend to be exacerbated and legitimized through work, the CSI-W echoes the warning issued by Young (1958) that meritocratic ideologies can lead to the legitimization of social inequalities. We're not suggesting that organizations should not strive to be meritocratic and distribute opportunities and rewards based on merit, but organizations should not be naïve in assuming that such distributions are free from bias. Meritocracy is not necessarily a myth, but in line with Young's original meaning of the term, the CSI-W indicates that meritocracy can easily become a cover-up for systems in which social inequalities accumulate. Before discussing what organizations can do to avoid such pitfalls of the meritocratic ideal, we first outline a number of suggestions for future research.

Directions for future research

In synthesizing current knowledge, the CSI-W calls for more research on the dynamics of social (in)equality in organizations. Such research should focus on both the content and the context of social inequality mechanisms. In terms of content, it should help to test individual mechanisms as well as examine potential interactions among mechanisms and their dynamics. In terms of context, it should focus on when and how the mechanisms are likely to be active, that is, the conditions of these mechanisms. In the following, we propose a particular way of how such research can be conducted. After that, we briefly highlight the need for research on the boundary conditions and mitigating factors of the different mechanisms and the CSI-W model as a whole.

Empirical examinations of the CSI-W model

We have argued that research on diversity and inequality in organizations has tended to overlook the dynamics of social inequality over time because it has adopted a largely static approach. To test our CSI-W model and more generally the cumulative dynamics of social inequality, different approaches and methods are needed. Specifically, we propose that looking at age-intersectionality may be a valuable approach. Age-intersectionality refers to the combination of age and other social identities (e.g., gender, educational level, ethnicity, socio-economic status (SES), occupational group, family status, and type of contract; Marcus & Fritzsche, 2015). Because age is inherently temporal, the use of age as a referent characteristic enables the identification of cumulative dynamics of social inequality (cf. Dannefer, 2003; Lawrence, 1984). In addition, an age-intersectionality approach allows longitudinal/temporal comparisons regarding the effects of important transitions (e.g., from one job to the next) and turning points (e.g., becoming a parent) on whether and, if so, how they inhibit or exacerbate social inequality in workplaces (cf. critical juncture theory; Capoccia & Kelemen, 2007). Using age as a referent characteristic thus allows to adopt a work life course perspective that focuses on the causes and consequences of events and experiences over time. This enables drawing comparisons between members of different groups within age categories as well as across age categories to assess potential path dependencies and dynamics in social inequality over time. For example, the CSI-W model proposes that social inequality between male and female workers will increase with age over time, and consequently that social inequality between older male and female workers is larger than social inequality between younger male and female workers. This difference in social inequality could be the result of the female workers having experienced negative career kicks (e.g., no opportunities for development) at

early stages of their career in a core organization, which for instance has led them to decide to work part-time in a peripheral organization.

An additional advantage of adopting an age-intersectionality approach is that it allows flexibility regarding the social categories being studied and matching that with the specific study context, while at the same time facilitating the integration and generalization of findings using age as the referent characteristic. The CSI-W model suggests that the best choice is to focus on those social categories that tend to be linked to performance expectations in a particular task context (Berger et al., 1974; Leslie, 2017; van Dijk & van Engen, 2013), given that they are most likely tied to cumulative social inequality outcomes over time. It thus suggests that, for example, the more language proficiency matters, the more nationality is likely to be a salient social category (cf. Neeley, 2013). At the same time, using age as the referent characteristic and looking at the specific age and life stage of the participants in those studies, researchers can place the findings of earlier studies in a larger context. This can enable researchers to identify the extent to which findings of social inequality fit into a larger temporal perspective and may be explained by experiences earlier in the (working) life course (e.g., Lawrence, 1984, 1988).

Based on the CSI-W model, we argue that it may also be particularly interesting to examine intersections of social categories with hierarchical position. An individual's position in the hierarchy tends to be a strong determinant of their status and social capital (Magee & Galinsky, 2008). As a consequence, when social inequality accumulates to the point that individuals belonging to, for example, advantaged groups are disproportionately promoted to positions higher in the hierarchy than disadvantaged group members, this will create a strong fault line (i.e., a hypothetical dividing line that splits social units into relatively homogeneous subgroups based on the distribution of multiple attributes; Lau & Murnighan, 1998; Meyer et al., 2014), which is

likely to exacerbate social inequality over time. In other words, we expect that promotions serve as accelerators in the accumulation of social inequality in workplaces and that this will become prominent by looking at intersections between social categories and hierarchical positions.

We direct researchers who wish to examine the latent causes of CSI-W by focusing on everyday occurrences and behaviors to the research area on microaggressions (Basford et al., 2014; Sue et al., 2009). Microaggressions refer to brief, everyday exchanges that send denigrating messages because targets belong to a certain group. Examples involve dismissive looks, gestures, and tones. Because they are often delivered automatically and subconsciously, they are often dismissed as being innocent. However, the literature on microaggressions suggests that repeated experiences of being overlooked, disrespected, and devalued based on one's social group membership can be experienced as overt and harmful because of their cumulative nature (Sue et al., 2008). As such, research on microaggressions provides a useful perspective to examine how everyday occurrences and behaviors can contribute to the accumulation of social inequality in workplaces.

A fruitful method for examining the cumulative nature of the social inequality mechanisms identified in the CSI-W model is sequence analysis, a set of methods for the quantitative analysis of ordered events, states, or occurrences (e.g., Bakeman & Gottman, 1997; Gabadinho et al., 2011). One set of ordered events or states, for example, the employment status history of an individual, is called a sequence. Across all sequences, the set of all events that occur at least once is called the alphabet of states. Sequential-analytical methods allow quantifying features of sequences such as transition probabilities and frequencies, which can be grouped based on further individual-level data. For example, sequence analysis can quantify the average likelihood of getting a promotion for a given social group at a given age. Sequence-analytical techniques also

allow to cluster event sequences based on similarity with optimal matching techniques (e.g., Biemann & Datta, 2014). In other words, these methods can identify whether event sequences such as career trajectories are similar or different across social groups (for an example, see Biemann et al., 2012). These techniques also allow to determine whether the occurrence of earlier events (e.g., receiving an opportunity or a reward) affects the likelihood of subsequent events. Therefore, from a methodological perspective, methods from the realm of sequence analysis are very suitable for investigating the dynamics of social inequality over time. Some organizational researchers have used sequence analysis for investigating behavior in career development (where career stages comprise the alphabet; see Biemann & Datta, 2014). However, to our knowledge, no empirical research has applied these techniques to investigate trajectories of accumulating social inequality in workplaces.

Another methodological approach lending itself to analyzing antecedents and consequences of career trajectories is latent growth modeling (LGM, also called latent growth curve modeling; e.g., Preacher, 2008). In LGM, variances in the intercept and slope of repeated measures over time are modeled as latent individual-level variables that can have relationships to other independent and dependent variables in larger structural equation models. For example, a researcher could collect study participants' annual salary over a period of several years as a numeric measure for career success. The researcher could subsequently model variations among the initial or average salaries with a latent intercept and variation in the salaries' temporal trajectories with a latent slope. The researcher could then regress these latent variables on variables operationalizing social group membership while controlling for others.

Mitigating factors

Although the CSI-W model focuses on the cumulative nature of social (in)equality, it is

likely that there is a limit to the extent to which social inequality accumulates over time in workplaces, if only because of floor effects (e.g., legislation prohibiting discrimination and proscribing minimum wage) and ceiling effects (e.g., finite levels and positions available in the organizational hierarchy; cf. Stewman & Konda, 1983). Understanding the nature of such mitigating factors is not only important for gaining a better understanding of the limits of the mechanisms in the CSI-W model, it also facilitates insight into how to offset the mechanisms, which may be particularly relevant for those contributing to non-meritocratic causes of cumulative social inequality. Since our understanding of the factors that mitigate cumulative social inequality mechanisms can only go as far as our understanding of the constituent mechanisms (cf. DiPrete & Eirich, 2006), we call for future research to assess how the dynamics outlined in this article can be mitigated. We outline two potential mitigating factors to spur research into this area.

A first potential mitigating factor is human agency and resilience. Employees are not only products but also producers of social systems, and hence they also create situations and opportunities for themselves (Bandura, 2001; Singh et al., 2011). Life span psychologists distinguish between continuous or cumulative versus discontinuous or innovative processes that play a role during life course development (Baltes, 1987; Heckhausen & Schulz, 1993). These discontinuous processes result from intraindividual plasticity, leading to different types of behavior or developmental courses. For example, although institutional regulations may encourage employees to stay in their chosen occupation, some individuals decide to retrain at an older age after a setback to move to another occupation. As such, this factor may mitigate the motivation mechanism by making individuals more instead of less motivated by setbacks as well as mitigate the homophily mechanism by making individuals determined to join higher status social networks.

A second potential mitigating factor is the weak correlation between social categories (Blau, 1977). In networks that are composed of weakly linked social categories (in relation to, e.g., gender, educational level, ethnicity, or class), high homophily (e.g., regarding gender) is more likely to bring together individuals who differ in other social categories (e.g., regarding ethnicity). Thus, since differences in one social category among individuals may not or may only weakly relate to differences in other social categories among them, contacts or network ties serve as bridges among groups, promoting intergroup relations and mitigating the homogenization of networks (Blau, 1977; DiMaggio & Garip, 2012). Moreover, the ties between networks are likely to provide new insights and information (Granovetter, 1973), which may be particularly helpful for individuals with weaker social capital given that such “weak ties” can grant them access to networks with more social capital.

Practical implications

When individuals, based on their social category membership, receive advantages that others do not, the CSI-W model indicates that such initial social inequality creates dynamics in workplaces that lead to the further accumulation of social inequality over time. This is not just problematic from a social justice perspective, as it also implies that the KSAs of disadvantaged members are underutilized at best (Mor Barak, 2016), which lowers their performance and inhibits organizations to reap the potential synergetic effects from diversity (Dwertmann et al., 2016; van Dijk et al., 2017). As a consequence, we argue that striving for more social equality in the workplace is not only important for individuals who would otherwise be disadvantaged based on their social categories but also for the organization at large. Proactively striving for social equality helps to avoid the pitfalls of meritocracy and fosters inclusion that can enhance the performance of

individuals as well as the organization at large (van Dijk & van Engen, 2019). In part, the question of how organizations can strive for social equality requires a better understanding of the factors that mitigate the cumulative dynamics of social inequality in workplaces and thus necessitates further research. However, based on the CSI-W model, there are already a number of suggestions we can offer to create more equal and inclusive organizations.

In general, the CSI-W model indicates that cumulative social inequality dynamics can be set in motion and strengthened over time via different mechanisms. These mechanisms are often not the result of conscious policies or decisions, nor are they always non-meritocratic. However, they can create non-merit-based social inequality over time. It is therefore important for organizations to be aware of these mechanisms and to consider the extent to which policies and practices implemented in the day-to-day behaviors and activities in the organization contribute to cumulative social inequality. For example, the CSI-W model suggests that social inequality is more likely to accumulate in organizations where there is a stronger occupational segmentation, where structures can be characterized as “winner-take-all,” and that endorse a meritocratic ideology. To organizations that wish to pursue social equality, the CSI-W model suggests that reducing occupational segmentation and the “winner-take-all” nature of structures and being more self-critical toward the meritocratic ideology would help them to attain that goal. Instead of a meritocratic ideology, for example, a strengths-based approach that focuses on identifying, developing, and using strengths of all employees could be adopted (e.g., Meyers & van Woerkom, 2014).

More complex are the ways in which mechanisms at the individual, dyadic, and network levels influence performance, opportunities, and rewards. The CSI-W model clearly shows that performance is not only the result of the capabilities of the individual employee and that differences in KSAs may also be spurred by social inequality. As such, fairly judging and

rewarding performance based on merit without bias is almost impossible. Even more worrisome is the observation that the cumulative nature of the mechanisms outlined in our CSI-W model suggests that they result in a self-fulfilling prophecy, causing evaluators to erroneously conclude that, for example, disadvantaged group members are lower performers and therefore legitimately granted fewer opportunities and rewards (cf. van Dijk et al., 2017). In fact, given the culturally shared interpretation of social categories (Ridgeway, 1991), it may be that even disadvantaged group members themselves come to interpret their lower performance as a confirmation of their lower merit and value to the organization. In such a situation, disadvantaged group members can be considered as institutionalized into social inequality—they would not even recognize it if there are unfair policies and practices in place because they would consider them as legitimately distinguishing between more versus less valuable group members (cf. Major & Kaiser, 2017; Rudman & Fairchild, 2004).

We therefore argue that surveying employees may not be the best way to assess the inclusiveness of an organization (as is common in research on diversity climates) and that practitioners interested in improving the level of inclusion should, at least in addition to such surveys, look for hard evidence of accumulating social inequality in the organization (e.g., such as shown in Figure 2). Where there is an indication that at higher levels the organization becomes more homogeneous in terms of social categories, it is likely that cumulative social inequality mechanisms are in operation. The CSI-W model suggests that identifying the social category (or categories) that are relevant can offer an understanding of which social groups tend to experience a cumulative advantage and which social groups tend to experience a cumulative disadvantage. Practitioners can use the CSI-W model to further identify which of the mechanisms are the main contributors to

the cumulative social inequality and consider ways to address this.

In summary, based on the findings from our integrative review, we assert that it is of utmost importance that evaluators are aware of the potential biases in trying to assess the merit (i.e., unbiased performance) of individual employees. However, it is very unlikely that these biases can be fully overcome (Feldman, 1981; Martell, 1991; Stauffer & Buckley, 2005), while the biggest issue is that evaluators might not even be aware of those mechanisms unconsciously influencing their evaluations. This unawareness makes them overly confident about the legitimacy of decisions and the resulting outcomes in terms of rewards and opportunities for employees (Major & Kaiser, 2017), rationalizing possible social inequality that follows from this (Kahneman, 2011). Given the reinforcing effects of opportunities and rewards, we therefore consider it even more important that careful thought is given to the opportunities and rewards that individuals receive based on their performance evaluations. There are two radical approaches to this. The first is to disconnect opportunities and rewards from performance and instead base them on other criteria or provide opportunities and rewards equally to all employees. The second is to provide separate opportunities and rewards packages for individuals based on their social categories, with more opportunities and rewards being made available for individuals belonging to societally more disadvantaged categories (cf. Noon, 2012). These radical approaches come with their own problems and are unlikely to be adopted by organizations (nor are we advocating that they should) but may help practitioners to consider less radical approaches when attempting to create more equal and inclusive workplaces for all.

Acknowledgment

The authors would like to thank Tanja Hentschel and the groups of Claudia Peus at Technical University of Munich and of Colette van Laar at KULeuven for their invaluable comments and suggestions for this article.

Funding

The author(s) received no financial support for the research, authorship, and/or publication of this article.

Author biographies

Hans van Dijk is an assistant professor of Organization Studies at Tilburg University in the Netherlands. He studies work group diversity and performance, inclusion, stereotyping, and social inequality, among others. He has developed an Inclusive Behavior Training that illustrates the point in this paper of how social inequalities are reinforced through everyday occurrences and behaviors.

Dorien Kooij is a professor of Human Resource Studies at the Department of Human

Resource Studies of Tilburg University in the Netherlands. Her research focuses on aging at work, and in particular on HR practices for older workers, on how work motivation changes with aging, on job crafting, and on future time perspective. She has published in international peer reviewed journals such as *Journal of Applied Psychology*, *Journal of Organizational Behavior*, *Industrial and Organizational Psychology: Perspectives on Science and Practice*, and *Psychology and Aging*.

Maria Karanika-Murray is an associate professor of occupational health psychology at Nottingham Trent University. She studies workplace health, well-being and performance; sickness presenteeism; and organizational health interventions, among others. She received her PhD from the University of Nottingham. Her research has been supported by the European Commission, UK Research Council, industry, and charity funds, and she has

acted as advisor to government and funding bodies in the UK and in Europe.

Ans De Vos is the SD Worx professor on Sustainable Careers at the Antwerp Management School and professor at the University of Antwerp in Belgium. She received her PhD in management from the University of Ghent, Belgium. She investigates careers at the intersection of individuals and organizations and the conditions that affect the sustainability of careers over time.

Bertolt Meyer is a professor of work and organizational psychology at Technische Universität Chemnitz in Germany. His research focuses on diversity at the workplace, leadership, health and wellbeing, and how technology changes the workspace and society as a whole. Next to that, he is an advocate for R and teaches numerous R courses at different universities.
